An oncolytic virus delivering tumor-irrelevant bystander T cell epitopes induces anti-tumor immunity and potentiates cancer immunotherapy

Tumor-specific T cells are crucial in anti-tumor immunity and act as targets for cancer immunotherapies. However, these cells are numerically scarce and functionally exhausted in the tumor microenvironment (TME), leading to inefficacious immunotherapies in most patients with cancer. By contrast, emerging evidence suggested that tumor-irrelevant bystander T (T_{BYS}) cells are abundant and preserve functional memory properties in the TME. To leverage T_{BYS} cells in the TME to eliminate tumor cells, we engineered oncolytic virus (OV) encoding T_{BYS} epitopes (OV-BYTE) to redirect the antigen specificity of tumor cells to pre-existing T_{BYS} cells, leading to effective tumor inhibition in multiple preclinical models. Mechanistically, OV-BYTE induced epitope spreading of tumor antigens to elicit more diverse tumor-specific T cell responses. Remarkably, the OV-BYTE strategy targeting human severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)-specific T cell memory efficiently inhibited tumor progression in a human tumor cell-derived xenograft model, providing important insights into the improvement of cancer immunotherapies in a large population with a history of SARS-CoV-2 infection or coronavirus disease 2019 (COVID-19) vaccination.

After acute infections or vaccinations, memory T (T_{MEM}) cells form and provide long-term protection against cognate pathogens[1]. By contrast, the functional exhaustion of T cells has been well characterized in many chronic infections and cancers[2]. Tumor-infiltrating CD8[+] T cells that specifically recognize tumor antigens manifest typical exhaustion-associated phenotypes, including progressive loss of effector functions, proliferative capacities and memory potential, while having elevated and sustained expression of a cluster of inhibitory immune checkpoint receptors (for example, PD-1, CTLA-4 and TIM-3)[2]. Blocking antibodies targeting these inhibitory immune checkpoint receptors, termed immune checkpoint blockade (ICB), can reinvigorate exhausted CD8[+] T (T_{EX}) cells in the TME, which thus lays

the foundation for the clinical effects of ICB. Although ICB therapies targeting PD-1–programmed cell death ligand 1 (PD-L1) interaction have documented durable remissions in a subset of patients with cancer, the overall response rates remain modest and even inert in certain cancer types[3], which might be partially explained by the fact that ICB therapies do not fundamentally alter the exhaustion-inherited epigenetic program in T_{EX} cells and fail to reprogram these cells to differentiate into T_{MEM} cells[4,5].

Accumulating evidence has suggested that the specific recognition of tumor-derived antigens is restricted to a minor proportion of tumor-infiltrating T cells, while the vast majority of tumor-infiltrating T cells recognize tumor-irrelevant antigens, especially common viral antigens, and are thus defined as 'T_{BYS} cells' (refs. [6–15]). Tumor-infiltrating T_{BYS} cells were reported to exhibit T_{MEM}-associated phenotypes[9,12,14,15]; however, their detailed differentiation states are not well characterized. Particularly, it remains unknown whether CD8+ T_{BYS} cells and CD4+ ones share similar memory traits in the TME. Furthermore, owing to the overwhelming number and function of T_{BYS} cells compared to tumor-specific T_{EX} cells in the TME, it would be of great therapeutic value if T_{BYS} cells in situ could be repurposed to eliminate tumor cells.

OV represents a highly versatile platform in delivering various payloads into tumor cells[16,17]. Many DNA or RNA viruses with potent tumor tropism have been proposed as vectors for OV immunotherapies, such as herpes simplex virus (HSV), adenovirus and Newcastle disease virus (NDV)[16,17]. To this day, OV immunotherapies have been investigated in ~100 reported clinical trials, in which the modified HSV encoding granulocyte–macrophage colony-stimulating factor (termed T-VEC) has been approved by the US Food and Drug Administration[17] and another triple-mutated HSV (termed as G47Δ) has been approved to treat recurrent glioblastoma in Japan[18]. It remains unknown whether OV can be exploited to drive tumor cells to present T_{BYS} cell-specific antigens, thus causing tumor cells to be eradicated by T_{BYS} cells of functional memory properties in the TME.

Results

Features of tumor-infiltrating virus-specific T_{BYS} cells

Although virus-specific T_{BYS} cells have been reported by accumulating evidence[6–15], a detailed portrait of these specialized T cells, especially CD4+ T_{BYS} cells, is lacking. We thus sought to analyze the kinetics, molecular characteristics and lineage relationship with other memory types of both CD8+ and CD4+ T_{BYS} populations in the TME. To this end, congenic naive (CD45.1+CD44loCD62Lhi) P14 CD8+ T cells recognizing the lymphocytic choriomeningitis virus (LCMV) glycoprotein (GP) epitope

H-2DbGP$_{33–41}$ and congenic naive (CD45.1+CD44loCD62Lhi) SMARTA (SM) CD4+ T cells recognizing the LCMV GP epitope I-AbGP$_{66–77}$ were adoptively transferred into C57BL/6 recipients (CD45.2+), which were then infected with LCMV Armstrong to establish acute viral infection and resultant virus-specific P14 T_{MEM} and SM T_{MEM} cells. On day 60 after infection, recipients were subcutaneously engrafted with syngeneic MC38 colon adenocarcinoma cells and tumor-infiltrating P14 CD8+ and SM CD4+ T cells, and T_{BYS} populations were analyzed on days 10, 15 and 20 after tumor engraftment (Fig. 1a and Extended Data Fig. 1a). As shown, frequencies of tumor-infiltrating P14 T_{BYS} and SM T_{BYS} cells remained stable at the different indicated time points (Fig. 1b,c), suggesting that the infiltrating virus-specific T_{BYS} cells were not altered at the population level during tumor progression.

Next, we set out to compare the molecular characteristics of virus-specific CD8+ T_{BYS} cells with their counterparts recognizing the same epitope but induced to differentiate into T_{MEM} or T_{EX} cells. Accordingly, congenic naive P14 CD8+ T cells were adoptively transferred into C57BL/6 recipients, which were infected with the LCMV Armstrong strain to induce the differentiation of P14 T_{MEM} cells. Furthermore, a fraction of these infected recipients was subcutaneously engrafted with MC38 cells on day 60 after infection, and tumor-infiltrating P14 T_{BYS} cells were analyzed on day 10 after tumor engraftment. In the scenario of tumor-specific T_{EX} cells, congenic naive P14 CD8+ T cells were adoptively transferred into C57BL/6 recipients, which were then subcutaneously engrafted with syngeneic B16F10 melanoma cells expressing the LCMV GP (hereafter referred to as B16-GP cells)[19] and killed on day 15 after tumor engraftment to analyze tumor-specific P14 T_{EX} cells (Extended Data Fig. 1b).

Resembling P14 T_{MEM} cells, we found that P14 T_{BYS} cells are mainly populated by the killer cell lectin-like receptor G1 (KLRG1)loCD127hi subset[1] (Fig. 1d). Furthermore, P14 T_{BYS} cells retain an expression pattern of transcription factors similar to that of P14 T_{MEM} cells[1], as exemplified by high expression of TCF-1 and Eomes and low expression of T-bet (Fig. 1e). In contrast to T_{MEM} cells, T_{EX} cells are characterized by coexpression of multiple inhibitory receptors, impaired cytokine secretion and the transcription factor TOX associated with T cell exhaustion[2,20–23]. Although preserved in the immunosuppressive TME, P14 T_{BYS} cells show limited expression of inhibitory receptors and TOX and exhibit polyfunctional cytokine secretion upon ex vivo re-stimulation (Fig. 1d,e). Thus, these findings confirm that CD8+ T_{BYS} cells phenotypically and functionally resemble CD8+ T_{MEM} cells but not CD8+ T_{EX} cells.

To further define the molecular traits of CD8+ T_{BYS} cells, we performed single-cell RNA sequencing (scRNA-seq) of P14 T_{BYS} cells

Fig. 1 | Features of tumor-infiltrating virus-specific T_{BYS} cells. a, Schematic of the experimental design. Congenic CD45.1+ P14 CD8+ T cells and CD45.1+ SM CD4+ T cells were adoptively transferred into naive C57BL/6 recipients (CD45.2+), which were then infected with LCMV Armstrong and engrafted with MC38 cells on day (D)60 after infection. On days 10, 15 and 20 after tumor engraftment, tumor-infiltrating P14 and SM cells were analyzed. **b**, Flow cytometry analysis of MC38 tumor-infiltrating CD8+ (top) and CD4+ (bottom) T cells on days 10, 15 and 20 after tumor engraftment. Numbers adjacent to the outlined areas indicate percentages of CD45.1+Vα2+ P14 cells (blue) of tumor-infiltrating CD8+ T cells or CD45.1+Vα2+ SM cells (red) of tumor-infiltrating CD4+ T cells. **c**, Frequency of P14 T_{BYS} cells of total MC38 tumor-infiltrating CD8+ T cells (indicated by blue dots, $n = 5$ mice (day 10) or $n = 4$ mice (day 15 and day 20)) and frequency of SM T_{BYS} cells of total MC38 tumor-infiltrating CD4+ T cells (indicated by red cubes, $n = 5$ mice (day 10) or $n = 4$ mice (day 15 and day 20)) at the indicated time points. **d**, Frequencies of P14 T_{MEM}, P14 T_{EX} and P14 T_{BYS} cells that express KLRG1 and/or CD127 (top; $n = 4$ mice (P14 T_{MEM}), $n = 3$ mice (P14 T_{EX}) or $n = 5$ mice (P14 T_{BYS})), coexpress the indicated number of inhibitory receptors (PD-1, TIM-3, LAG-3 and 2B4) (middle; $n = 5$ mice (P14 T_{MEM}), $n = 3$ mice (P14 T_{EX}) or $n = 4$ mice (P14 T_{BYS})) or coexpress the indicated number of cytokines (IFN-γ and tumor necrosis factor (TNF)-α) and cytotoxic degranulation markers (CD107a and CD107b) (bottom; $n = 5$ mice (P14 T_{MEM}), $n = 3$ mice (P14 T_{EX}) or $n = 3$ mice (P14 T_{BYS})). **e**, Comparison of TCF-1, Eomes, T-bet and TOX expression levels among P14 T_{MEM} ($n = 3$ mice),

P14 T_{EX} ($n = 3$ mice) and P14 T_{BYS} cells ($n = 5$ mice). MFI, mean fluorescence intensity. **f**, A Radviz projection of P14 T_{MEM}, P14 T_{RM} (kidney, liver, salivary gland (SG) and small intestine intra-epithelial lymphocyte (siIEL)) and P14 T_{BYS} cells based on nine gene expression programs (Pro_1–Pro_9) inferred by consensus non-negative matrix factorization. A total of 38,880 P14 cells passed quality control. **g**, Heatmap showing selected DEGs in various P14 cells. **h**, UMAPs of SM T_{BYS} (left) and SM T_{MEM} cells (right). A total of 3,565 SM T_{BYS} cells are colored in yellow, and a total of 5,648 SM T_{MEM} cells are colored in blue. **i**, UMAPs showing expression levels of *Ly6c2*, *Gzmb*, *Foxp3* and *Cxcr5* in SM T_{BYS} and SM T_{MEM} cells. **j**, Frequency of SM T_{MEM}, SM T_{TST} and SM T_{BYS} cells that coexpress the indicated number of inhibitory receptors (PD-1, TIM-3, LAG-3 and 2B4) (top; $n = 3$ mice (SM T_{MEM}), $n = 3$ mice (SM T_{TST}) or $n = 3$ mice (SM T_{BYS})) or coexpress the indicated number of cytokines (IFN-γ and TNF-α) and cytotoxic degranulation markers (CD107a and CD107b) (bottom; $n = 3$ mice (SM T_{MEM}), $n = 3$ mice (SM T_{TST}) or $n = 5$ mice (SM T_{BYS})). **k**, Comparison of TCF-1, Eomes, T-bet and TOX expression levels among SM T_{MEM} ($n = 3$ mice), SM T_{TST} ($n = 3$ mice) and SM T_{BYS} ($n = 5$ mice) cells. TFs, transcription factors. **l**, Gene set scoring analysis of 3,565 SM T_{BYS} cells and 5,648 SM T_{MEM} cells. Density of cells in the T_{CM} versus T_{RM} score space annotated by cell type is depicted. **m**, Expression profiles of *Cd69*, *Rgs1*, *Nr4a1* and *Bhlhe40* of SM T_{BYS} and SM T_{MEM} cells in the T_{CM} versus T_{RM} score space. Data (**b–e,j,k**) are representative of two independent experiments. One-way ANOVA with Turkey's test was used in **e,k**. Center values and error bars (**c,e,k**) indicate mean and s.e.m.

from the TME of MC38-engrafted mice. Conventional P14 T_{MEM} and tissue-resident memory (T_{RM}) cells from external scRNA-seq datasets[24,25] were introduced as controls (Extended Data Fig. 1c). A Radviz

projection based on nine gene expression programs inferred by consensus non-negative matrix factorization clearly distinguished P14 T_{MEM} cells from P14 T_{RM} cells of various non-lymphoid tissues (Fig. 1f
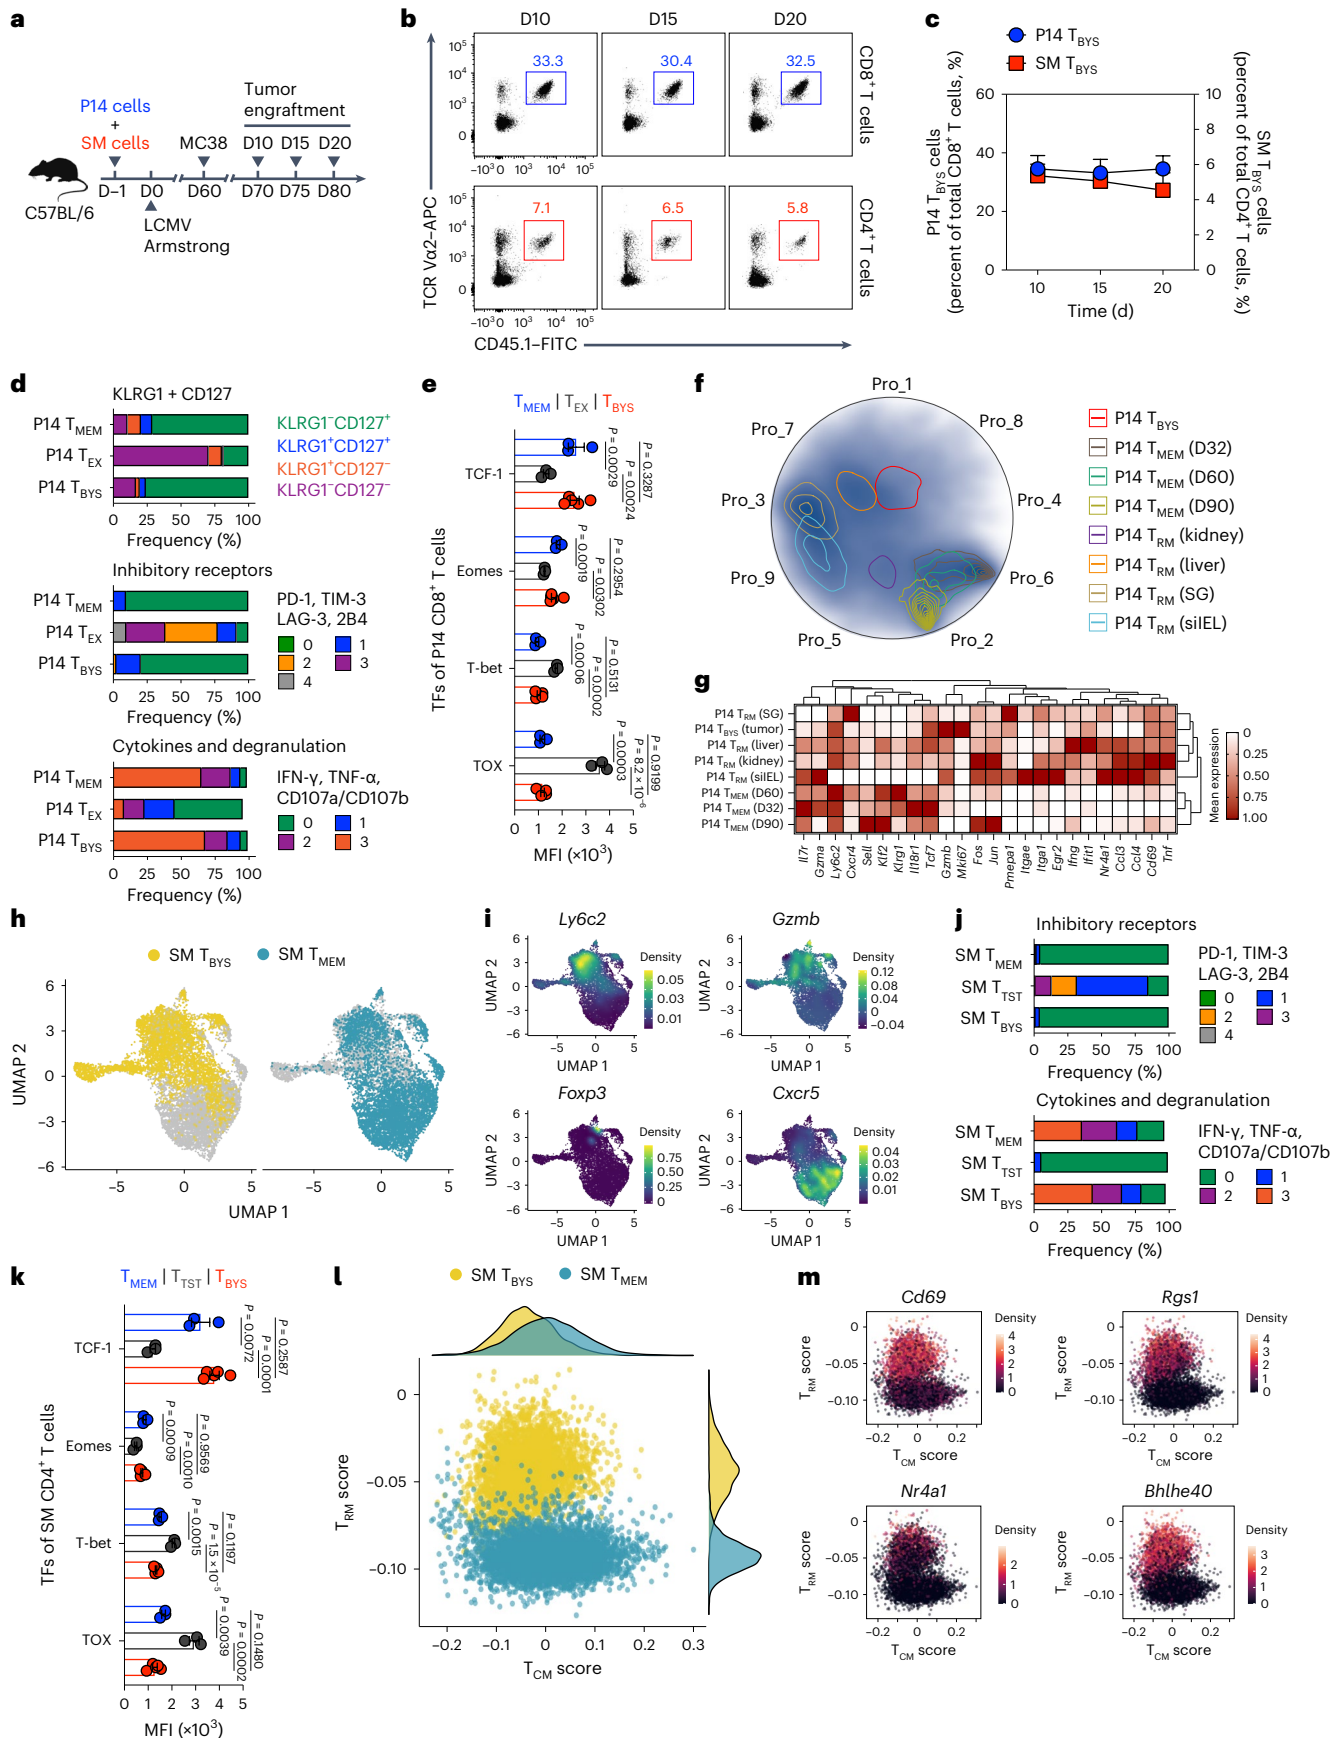

and Extended Data Fig. 1d,e). Importantly, P14 T_{BYS} cells were drawn toward the groups of P14 T_{RM} cells (Fig. 1f), likely representing the acquisition of certain T_{RM} cell features. Further unbiased hierarchical clustering confirmed that P14 T_{BYS} cells are in close proximity with P14 T_{RM} cells and highlighted by cytolytic activity (*Gzmb*, *Tnf*) and tissue residency (*Cd69*, *Nr4a1*)[26] (Fig. 1g). The potential residency of P14 T_{BYS} cells was also evidenced by high expression of CD69 protein (Extended Data Fig. 2a,b). Therefore, these findings suggest T_{RM} cell features of CD8[+] T_{BYS} cells.

Next, we aimed to trace the differentiation of virus-specific CD4[+] T_{BYS} cells by performing scRNA-seq of SM T_{BYS} cells from the MC38 TME with conventional SM T_{MEM} cells as controls (Extended Data Fig. 1c). Consistent with previous studies[27,28], SM T_{MEM} cells adopt a bifurcation of follicular helper T cells (*Cxcr5*) and type 1 helper T (T_H1) cells (*Ly6c2*, *Gzmb*) (Fig. 1h,i). Instead of adopting a follicular helper T/T_H1 bifurcation, we found that SM T_{BYS} cells were predominantly fated toward the T_H1 lineage (Fig. 1h,i). Indeed, T_H1-type SM T_{BYS} cell differentiation was further evidenced by abundant Ly6C protein but rare expression of C−X−C motif chemokine receptor (CXCR)5 (Extended Data Fig. 2c−e). Furthermore, similar to P14 T_{BYS} cells, SM T_{BYS} cells also showed high expression of TCF-1 and Eomes and low expression of T-bet (Fig. 1k), suggesting the retention of memory properties. In addition, SM T_{BYS} cells showed no features related to exhaustion, including multiple inhibitory receptors[29] and TOX[30], as compared to tumor antigen-specific T (T_{TST}) cells (Fig. 1j,k); instead, SM T_{BYS} cells exhibit a substantial capacity to secrete multiple cytokines upon ex vivo re-stimulation (Fig. 1j). These results define the memory properties of T_H1-type CD4[+] T_{BYS} cells in the TME.

Previous studies stated distinct molecular signatures between central memory T (T_{CM}) and T_{RM} cells[31,32]. We therefore examined the enrichment for T_{CM} and T_{RM} cell gene signatures in SM T_{BYS} cells, with conventional SM T_{MEM} cells being introduced as controls, to explore the effector−memory state in the SM T_{BYS} population. We found a largely overlaid T_{CM} signature between SM T_{BYS} and SM T_{MEM} cells, with a noticeable dissection in the T_{RM} signature (Fig. 1l). Indeed, genes related to T_{RM} cells (for example, *Cd69*, *Rgs1*, *Nr4a1* and *Bhlhe40*) were highly

expressed in SM T_{BYS} cells relative to those in SM T_{MEM} cells (Fig. 1m); meanwhile, genes related to T_{CM} cells (for example, *Il7r*, *Tcf7* and *Ccr7*) were largely overlapping between SM T_{BYS} and SM T_{MEM} cells (Extended Data Fig. 2f). Distinct from SM T_{BYS} cells, P14 T_{BYS} cells were dominated by the gene signature of T_{RM} cells rather than that of T_{CM} cells (Extended Data Fig. 2g). Thus, these findings highlight a unique hybrid gene signature consisting of both T_{CM} and T_{RM} cell features in CD4[+] T_{BYS} cells but not in CD8[+] T_{BYS} cells.

We further explored endogenous virus-specific T_{BYS} cells from MC38 tumors engrafted in LCMV-infected mice by quantifying interferon (IFN)-γ-expressing cells upon ex vivo stimulation with cognate viral peptides (Extended Data Fig. 3a). Consistently, we observed the presence of endogenous CD8[+] T_{BYS} cells specific to LCMV GP$_{33−41}$, LCMV GP$_{276−286}$ and LCMV nucleoprotein (NP)$_{396−404}$ and endogenous CD4[+] T_{BYS} cells specific to LCMV GP$_{66−77}$ in the MC38 tumors engrafted in LCMV-infected mice (Extended Data Fig. 3b−e). In addition to the MC38 tumor model, endogenous LCMV-specific T_{BYS} cells were also found in the TME of B16F10-engrafted mice (Extended Data Fig. 3f−h). In sum, these findings highlight the functional memory characteristics of virus-specific CD8[+] and CD4[+] T_{BYS} cells in the TME.

OV-BYTE therapy elicits anti-tumor response

Given the abundant memory pool of virus-specific T_{BYS} cells in the TME, we hypothesized that OV-mediated delivery of T_{BYS} cell epitopes (hereafter referred to as OV-BYTE) to tumor cells might redirect the cytotoxicity of T_{BYS} cells toward tumor cells and thus curtail tumor progression. For this purpose, the gene encoding LCMV GP was inserted into an NDV rSG10 strain (referred to as NDV wild type (WT)) and thus termed NDV-GP (Extended Data Fig. 4a). To assess the ability of NDV-GP to infect and deliver LCMV GP expression in tumor cells, we infected MC38 cells with NDV-GP and then detected LCMV GP expression in the infected MC38 cells. In accordance with the previously reported highly efficient transgene delivery of oncolytic NDV[33,34], we found that NDV-GP substantially infected MC38 cells and expressed the LCMV GP transgene (Extended Data Fig. 4b−d). Furthermore, we also found enhanced expression of major histocompatibility complex (MHC)-I and

Fig. 2 | OV-mediated delivery of T_{BYS} cell epitopes to solid tumor cells elicits anti-tumor response. a, Schematic of the experimental design for **b,c**. C57BL/6 mice were infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On days 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally administered PBS, NDV-WT or NDV-GP. **b,c**, Tumor growth curve (**b**) and Kaplan−Meier survival curve (**c**) of MC38 tumor-bearing mice intratumorally treated with PBS (*n* = 6 mice), NDV-WT (*n* = 10 mice) or NDV-GP (*n* = 10 mice) as described in **a. d**, Schematic of the experimental design for **e**. NCG mice were engrafted with PBMCs from HLA-A2-positive donors with a history of H1N1 infection. After reconstruction of human T cells, these humanized NCG mice were engrafted with A375 cells and then intratumorally administered PBS, NDV-WT or NDV-H1N1 NP on days 7, 8, 9, 11 and 12 after tumor engraftment. **q,r**, Tumor growth curve (**q**) and Kaplan−Meier survival curve (**r**) of A375 tumor-bearing humanized NCG mice intratumorally treated with PBS (*n* = 5 mice), NDV-WT (*n* = 6 mice) or NDV-H1N1 NP (*n* = 5 mice) as described in **p**. All data are representative of at least two independent experiments. Two-way ANOVA was used to compare tumor growth curves in **b,g,q**. The log-rank (Mantel−Cox) test was performed to compare survival curves among groups in **c,e,i,k,m,o,r**. Center values and error bars (**b,g,q**) indicate mean and s.e.m.

MHC-II molecules in NDV-GP-infected tumor cells and specific killing of these tumor cells by LCMV GP-specific T cells (Extended Data Fig. 4e–g), indicating MHC presentation of LCMV GP epitopes by NDV-GP-infected tumor cells to LCMV GP-specific T cells.

Next, we aimed to assess the in vivo anti-tumor activities of NDV-GP in tumor-bearing mice that have established immune memory for LCMV. To this end, naive C57BL/6 mice were infected with LCMV

Armstrong, followed by subcutaneously engraftment with MC38 cells on day 60 after infection and then intratumoral treatment with phosphate-buffered saline (PBS), NDV-WT or NDV-GP (Fig. 2a). Remarkably, NDV-GP treatment delayed tumor growth more efficiently than NDV-WT treatment (Fig. 2b) and led to ~30% complete remission on day 50 after tumor engraftment (Fig. 2c). Moreover, NDV-GP treatment did not show any therapeutic advantages over NDV-WT treatment in
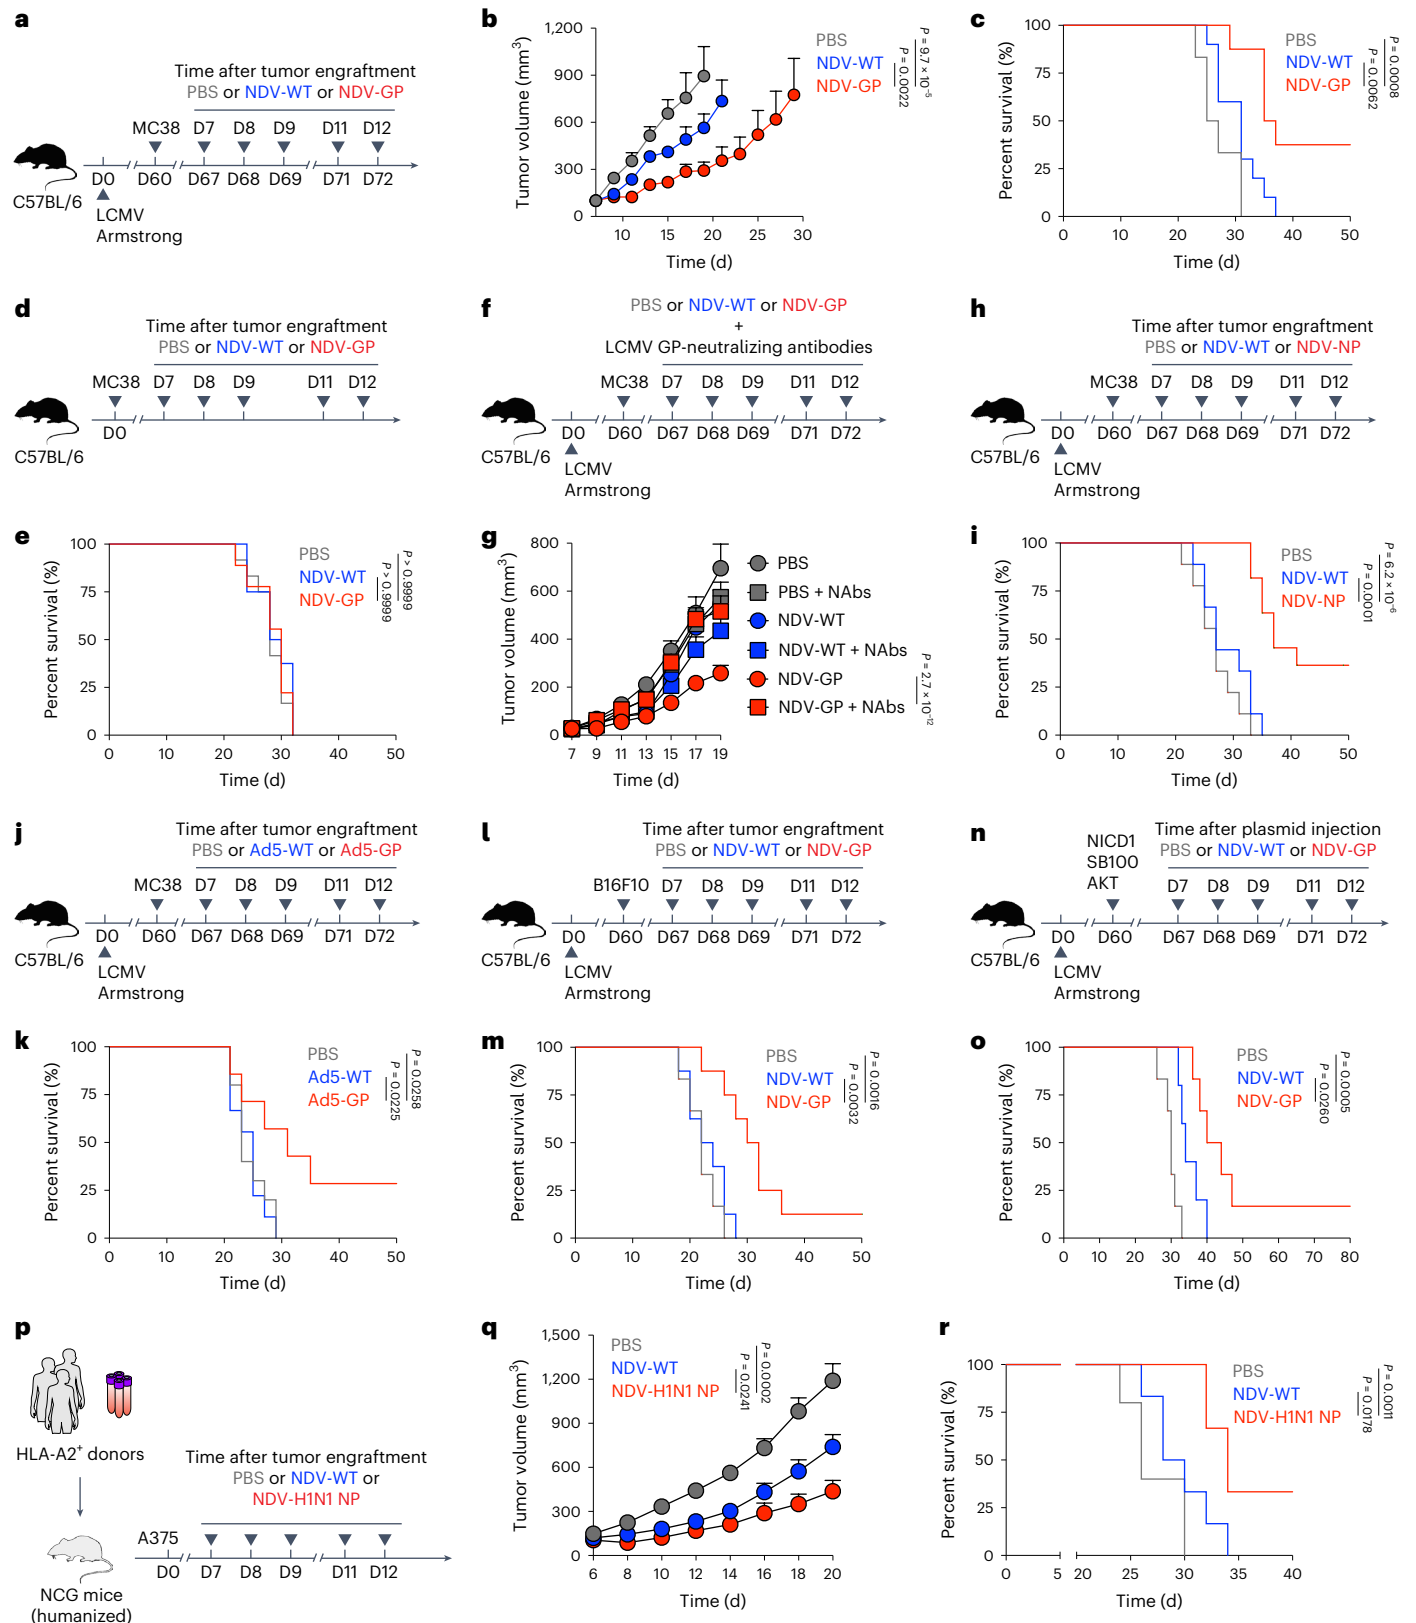

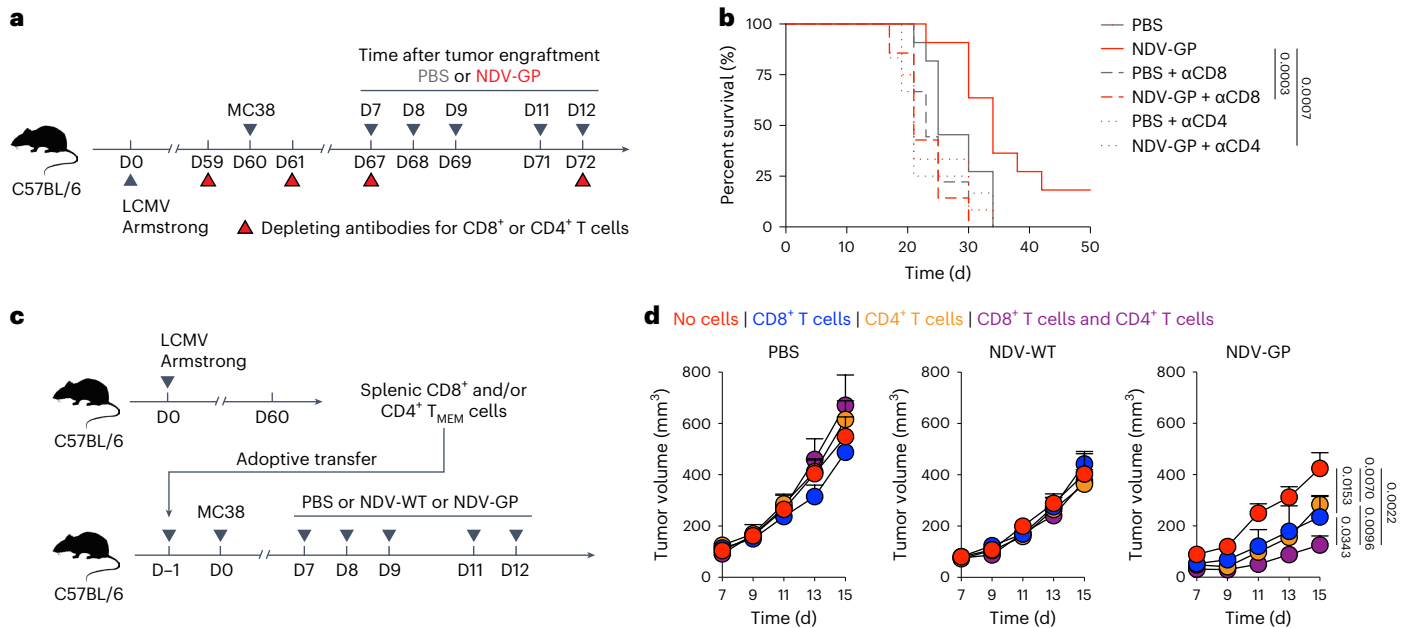

Fig. 3 | Anti-tumor effects of OV-BYTE therapy are attributed to both virus-specific CD8$^+$ and CD4$^+$ T$_{BYS}$ cells. a, Schematic of the experimental design for **b**. Naive C57BL/6 mice were infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On days 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally administered PBS, NDV-WT or NDV-GP. Meanwhile, recipients were intraperitoneally injected with depleting antibodies for CD8$^+$ or CD4$^+$ T cells at the indicated time points. **b**, Kaplan–Meier survival curve of MC38 tumor-bearing mice intratumorally treated with PBS or NDV-GP in the presence or absence of depleting antibody for CD8$^+$ (αCD8) or CD4$^+$ (αCD4) T cells as described in **a**. PBS ($n = 11$ mice), NDV-GP ($n = 11$ mice), PBS and anti-CD8 antibody ($n = 9$ mice), NDV-GP and anti-CD8 antibody ($n = 7$ mice), PBS and anti-CD4 antibody ($n = 12$ mice), NDV-GP and anti-CD4 antibody ($n = 12$ mice). **c**, Schematic of the experimental design for **d**. Splenic memory CD8$^+$ and/or CD4$^+$ T cells were collected from LCMV Armstrong-infected mice (day 60)

and adoptively transferred into naive C57BL/6 mice. These recipients were then subcutaneously engrafted with MC38 cells 1 day after adoptive cell transfer and intratumorally treated with PBS, NDV-WT or NDV-GP on days 7, 8, 9, 11 and 12 after tumor engraftment. **d**, Tumor growth curves of PBS (left; $n = 9$ (no cells), $n = 8$ (CD8$^+$ T cells), $n = 8$ (CD4$^+$ T cells) or $n = 8$ (CD8$^+$ T cells and CD4$^+$ T cells) mice), NDV-WT (middle; $n = 9$ (no cells), $n = 8$ (CD8$^+$ T cells), $n = 8$ (CD4$^+$ T cells) or $n = 9$ (CD8$^+$ T cells and CD4$^+$ T cells) mice) or NDV-GP (right; $n = 9$ (no cells), $n = 8$ (CD8$^+$ T cells), $n = 8$ (CD4$^+$ T cells) or $n = 5$ (CD8$^+$ T cells and CD4$^+$ T cells) mice) -treated MC38 tumor-bearing mice receiving adoptive transfer of LCMV Armstrong-activated CD8$^+$ and/or CD4$^+$ T cells or receiving no cell transfer as described in **c**. All data are representative of at least two independent experiments. The log-rank (Mantel–Cox) test was performed to compare survival curves among groups in **b**. Two-way ANOVA was used to compare tumor growth curves in **d**. Center values and error bars (**d**) indicate mean and s.e.m.

tumor-engrafted mice without pre-existing immune memory (Fig. 2d,e); meanwhile, the therapeutic function of NDV-GP to treat MC38 tumors engrafted in LCMV-infected mice was abolished in the presence of neutralizing antibodies specific to LCMV GP proteins (Fig. 2f,g).

In parallel, we also constructed the NDV strain carrying the LCMV NP gene (referred to as NDV-NP) to treat MC38-bearing mice with LCMV immune memory (Fig. 2h and Extended Data Fig. 4a,h). Similarly, NDV-NP treatment led to significant tumor growth delays compared to NDV-WT treatment and generated ~30% complete regression (Fig. 2i). To test whether another non-NDV OV platform could also be used to target T$_{BYS}$ cells to limit tumor progression, LCMV Armstrong-infected C57BL/6 mice were engrafted with MC38 cells and then intratumorally administered the oncolytic adenovirus serotype 5 (Ad5) that carries the LCMV GP gene (referred to here as Ad5-GP) (Fig. 2j and Extended Data Fig. 4i,j). Similarly, Ad5-GP treatment effectively slowed tumor growth and resulted in marked tumor regression (~25% complete regression) compared to control treatments (Fig. 2k).

In addition to MC38 colon adenocarcinoma, the therapeutic functions of NDV-GP were also evident in a B16F10 melanoma model of weak immunogenicity (Fig. 2l,m and Extended Data Fig. 4k). Aside from transplanted tumor models, NDV-GP administration also largely improved the survival rates of mice with LCMV memory and Notch intracellular domain (NICD)- and AKT-induced autochthonous intra-hepatic cholangiocarcinoma[35] (Fig. 2n,o), suggesting the potential efficacy of OV-BYTE therapy in different cancer types.

To more closely examine the clinical relevance of OV-BYTE therapy, we further recruited a cohort of human leukocyte antigen (HLA)-A2-positive healthy donors with a history of influenza A (H1N1)

infection (Extended Data Fig. 4l). The peripheral blood mononuclear cells (PBMCs) of these donors, which contain memory CD8$^+$ and CD4$^+$ T cells specific to the H1N1 NP epitope (Extended Data Fig. 4m,n), were used to develop humanized mice by engraftment of human PBMCs into NCG mice (Fig. 2p). Humanized NCG mice with an appropriate reconstruction of human T cells were engrafted with HLA-A2-matched A375 human melanoma cells to make a cell line-derived xenograft (CDX). Next, these CDX mice were intratumorally administered PBS, NDV-WT or the NDV strain expressing H1N1 NP (referred to as NDV-H1N1 NP) (Fig. 2p and Extended Data Fig. 4o). Remarkably, treatment with NDV-H1N1 NP restricted tumor growth of A375 melanoma and prolonged the overall survival of CDX mice (Fig. 2q,r). Together, these data demonstrate the potential anti-tumor functionality of OV-BYTE therapy.

OV-BYTE therapy is attributed to CD8$^+$ and CD4$^+$ T$_{BYS}$ cells

To determine the cellular mechanism(s) underlying OV-BYTE therapy, we next analyzed the composition of important immune cells within NDV-GP-administered MC38 tumors in mice with LCMV memory (Extended Data Fig. 5a). We found that numbers of CD45$^+$ immune cells were increased in tumors treated with NDV-GP compared with those of tumors treated with PBS or NDV-WT (Extended Data Fig. 5b). Moreover, the NDV-GP-mediated increased immune cell number was mainly attributed to T cells and dendritic cells (DCs) (Extended Data Fig. 5c). Further analysis of T cells revealed increased numbers of both CD8$^+$ and CD4$^+$ T cells in NDV-GP-treated tumors (Extended Data Fig. 5d). In addition, the ratio of CD8$^+$ T cells or conventional CD4$^+$ T cells to regulatory CD4$^+$ T cells was largely enhanced upon NDV-GP treatment

(Extended Data Fig. 5e–h). Thus, these findings suggest that NDV-GP treatment favors CD8$^+$ and CD4$^+$ T cell responses in the TME.

To decipher the contributions of CD8$^+$ and CD4$^+$ T cells to the therapeutic effects of NDV-GP administration, we carried out NDV-GP treatment with CD8$^+$ or CD4$^+$ T cell depletion (Fig. 3a). As shown, depletion of either CD8$^+$ or CD4$^+$ T cells similarly abolished the therapeutic effects of NDV-GP and led to a significant reduction in long-term survival of MC38 tumor-bearing mice with LCMV memory (Fig. 3b). To further confirm the important roles of virus-specific CD8$^+$ or CD4$^+$ T$_{BYS}$ cells in the OV-BYTE strategy, LCMV-specific memory CD8$^+$ and/or CD4$^+$ T cells were collected and adoptively transferred into naive C57BL/6 recipients, which were then engrafted with MC38 cells and intratumorally administered PBS, NDV-WT or NDV-GP (Fig. 3c). Compared to the NDV-GP-treated group with no T cell transfer, single adoptive transfer of memory CD8$^+$ or CD4$^+$ T cells resulted in limited tumor retardation in mice administered NDV-GP (Fig. 3d). Remarkably, the combined transfer of memory CD8$^+$ and CD4$^+$ T cells synergized to better control tumor growth in the NDV-GP-treated group than in monotransfer of memory CD8$^+$ or CD4$^+$ T cells (Fig. 3d). Nevertheless, the anti-tumor effects of LCMV-specific memory CD8$^+$ and/or CD4$^+$ T cell transfer were abolished upon PBS or NDV-WT treatment (Fig. 3d). Therefore, these observations indicate that OV-BYTE therapy can target virus-specific CD8$^+$ and CD4$^+$ T$_{BYS}$ cells and efficiently redirect their cytotoxicity toward tumor cells.

OV-BYTE therapy provokes cytotoxic CD4$^+$ T$_{BYS}$ cells

To ascertain how T$_{BYS}$ cells respond to OV-BYTE therapy, C57BL/6 mice initially receiving transfer of congenic P14 and SM cells were infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. After five injections of PBS, NDV-WT or NDV-GP, P14 and SM T$_{BYS}$ cells were analyzed (Fig. 4a). Notably, we found that both the frequency and number of total P14 T$_{BYS}$ cells were comparable among PBS, NDV-WT and NDV-GP groups in the TME (Fig. 4b). Consistently, NDV-GP treatment showed no effects in boosting the proliferation

of P14 T$_{BYS}$ cells (Fig. 4b). Similarly, the frequencies and numbers of endogenous CD8$^+$ T$_{BYS}$ cells specific to LCMV GP$_{33–41}$, GP$_{91–101}$, GP$_{118–125}$ and GP$_{276–286}$ were also not influenced by NDV-GP treatment (Extended Data Fig. 5i–m). These results highlighted characteristics similar between CD8$^+$ T$_{BYS}$ cells and T$_{RM}$ cells, both of which immediately differentiate into effector cells but with much less efficient expansion upon antigen rechallenge than T$_{CM}$ cells[36].

In the scenario of CD4$^+$ T$_{BYS}$ cells, we found that, in contrast to CD8$^+$ T$_{BYS}$ cells, NDV-GP treatment dramatically boosted both the frequency and number of SM T$_{BYS}$ cells, accompanied by increased cell proliferation (Fig. 4c). Consistently, endogenous LCMV GP$_{66–77}$-specific CD4$^+$ T$_{BYS}$ cells were also greatly expanded by NDV-GP treatment (Extended Data Fig. 5n). Thus, a biased robust increment of CD4$^+$ T$_{BYS}$ cells over CD8$^+$ T$_{BYS}$ cells is provoked by NDV-GP treatment.

Next, we sought to delineate the molecular patterns of NDV-GP-boosted T$_{BYS}$ cells in the TME. To this end, P14 and SM T$_{BYS}$ cells of MC38 tumors treated with PBS, NDV-WT or NDV-GP were used for scRNA-seq analyses (Fig. 4a). A total of eight clusters were identified by uniform manifold approximation and projection (UMAP) analysis and included four clusters populated by P14 T$_{BYS}$ cells (P14 clusters 1–4, C1–C4) and another four clusters populated by SM T$_{BYS}$ cells (SM C1–C4) (Fig. 4d,e). Within P14 T$_{BYS}$ cells, each cluster was evenly distributed among PBS-, NDV-WT- and NDV-GP-treated groups (Extended Data Fig. 6a,b). Moreover, we found minimally changed gene signatures in NDV-GP-treated P14 T$_{BYS}$ cells as compared to PBS- or NDV-WT-treated ones (Extended Data Fig. 6c), suggesting that NDV-GP administration may not fundamentally alter gene signatures in P14 T$_{BYS}$ cells of inherited T$_{RM}$ properties[32]. By contrast, cluster composition of SM T$_{BYS}$ cells was dramatically altered upon NDV-GP treatment, with which a pronounced enrichment of SM C2 was observed (Fig. 4d and Extended Data Fig. 6a,b). In agreement with the changed cluster composition, RNA velocity analysis further revealed a SM C2-directed differentiation in NDV-GP-educated SM T$_{BYS}$ cells (Extended Data Fig. 6d), suggesting that SM T$_{BYS}$ cells populating C2 might be unique responders to NDV-GP treatment.

Fig. 4 | OV-BYTE therapy expands and provokes the cytotoxic effector functions of virus-specific CD4$^+$ T$_{BYS}$ cells. a, Schematic of the experimental design. Congenic CD45.1$^+$ P14 CD8$^+$ T cells and CD45.1$^+$ SM CD4$^+$ T cells were adoptively transferred into naive C57BL/6 recipients (CD45.2$^+$), which were then infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On days 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally treated with PBS, NDV-WT or NDV-GP. On day 14 after tumor engraftment, tumor-infiltrating P14 and SM cells were analyzed. **b**, Frequency of P14 T$_{BYS}$ cells of tumor-infiltrating CD8$^+$ T cells (left), number of P14 T$_{BYS}$ cells (middle) and frequency of Ki-67$^+$ cells of P14 T$_{BYS}$ cells (right) from PBS ($n = 5$ mice), NDV-WT ($n = 6$ mice) and NDV-GP ($n = 5$ mice) -treated MC38 tumors. **c**, Frequency of SM T$_{BYS}$ cells of tumor-infiltrating CD4$^+$ T cells (left), number of SM T$_{BYS}$ cells (middle) and frequency of Ki-67$^+$ cells of SM T$_{BYS}$ cells (right) from PBS ($n = 5$ mice), NDV-WT ($n = 6$ mice) and NDV-GP ($n = 5$ mice) -treated MC38 tumors. **d**, UMAP analysis of P14 T$_{BYS}$ and SM T$_{BYS}$ cells upon PBS (left, 6,571 cells), NDV-WT (middle, 5,397 cells) or NDV-GP (right, 5,951 cells) treatment. **e**, Bubble chart showing selected genes in each cluster of P14 T$_{BYS}$ and SM T$_{BYS}$ cells as described in **d**. **f**, Volcano plot showing DEGs between SM C2 and SM C1 and SM C3 in **d**. FC, fold change; NS, not significant. **g**, Flow cytometry analysis of tumor-infiltrating SM T$_{BYS}$ cells from the PBS-, NDV-WT- or NDV-GP-treated group. Numbers adjacent to the outlined areas indicate percentages of GzmB$^+$ cells of the indicated PBS- or NDV-WT-treated SM T$_{BYS}$ cells or NDV-GP-treated TCF-1^{hi}T-bet^{lo} or TCF-1^{lo}T-bet^{hi} SM T$_{BYS}$ cells. **j**, Frequency of GzmB$^+$ cells of PBS ($n = 6$ mice) or NDV-WT ($n = 6$ mice) -treated SM T$_{BYS}$ cells or NDV-GP-treated ($n = 6$ mice) TCF-1^{hi}T-bet^{lo} or TCF-1^{lo}T-bet^{hi} SM T$_{BYS}$ cells. **k**, Ex vitro killing efficiency of SM T$_{BYS}$ cells from the PBS

($n = 3$ mice) or NDV-WT ($n = 3$ mice) -treated group and Ly108^{hi}CD39^{lo} or Ly108^{lo}CD39^{hi} SM T$_{BYS}$ cells from the NDV-GP-treated group ($n = 3$ mice). **l**, Schematic of the experimental design for **m**. Naive CD45.2$^+$ C57BL/6 mice receiving adoptive transfer of congenic CD45.1$^+$ SM CD4$^+$ T cells were infected with LCMV Armstrong and then engrafted with MC38 cells on day 60 after infection. On days 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally treated with NDV-GP. On day 14 after tumor engraftment, tumor-infiltrating Ly108^{hi}CD39^{lo} or Ly108^{lo}CD39^{hi} SM T$_{BYS}$ cells were isolated and transferred into a new cohort of C57BL/6 mice, which were not exposed to LCMV Armstrong and engrafted with MC38 cells 6 days before the SM T$_{BYS}$ cell transfer. These new recipients were next intratumorally administered PBS, NDV-WT or NDV-GP on day 7 to day 12 after tumor engraftment. **m**, Tumor growth curve of MC38 tumor-bearing mice treated with PBS, NDV-WT or NDV-GP upon Ly108^{hi}CD39^{lo} ($n = 10$ (PBS), $n = 10$ (NDV-WT) or $n = 10$ (NDV-GP) mice) or Ly108^{lo}CD39^{hi} ($n = 7$ (PBS), $n = 8$ (NDV-WT) or $n = 8$ (NDV-GP) mice) SM T$_{BYS}$ cell transfer or no cell ($n = 9$ (PBS), $n = 9$ (NDV-WT) or $n = 9$ (NDV-GP) mice) transfer as described in **l**. i.t., intratumoral. **n**, Schematic of the experimental design for **o**. Naive WT C57BL/6 mice and naive *Gzmb*^{KO} mice were infected with LCMV Armstrong. On day 60 after infection, splenic CD44$^+$CD127$^+$ memory CD4$^+$ T cells were isolated from WT or *Gzmb*^{KO} mice and then adoptively transferred into a new cohort of C57BL/6 mice. Next, these recipients were engrafted with MC38 cells and intratumorally treated with PBS, NDV-WT or NDV-GP on days 7, 8, 9, 11 and 12 after tumor inoculation. **o**, Tumor growth curve of MC38 tumor-bearing mice treated with PBS ($n = 9$ (no cells), $n = 8$ (WT CD4$^+$ T cells) or $n = 8$ (*Gzmb*^{KO} CD4$^+$ T cells) mice), NDV-WT ($n = 9$ (no cells), $n = 10$ (WT CD4$^+$ T cells) or $n = 9$ (*Gzmb*^{KO} CD4$^+$ T cells) mice) or NDV-GP ($n = 10$ (no cells), $n = 8$ (WT CD4$^+$ T cells) or $n = 10$ (*Gzmb*^{KO} CD4$^+$ T cells) mice) upon WT or *Gzmb*^{KO} memory CD4$^+$ T cell transfer or no cell transfer as described in **n**. Data (**b,c,g–k,m,o**) are representative of two independent experiments. One-way ANOVA with Turkey's test was used in **b,c,h,j,k**. The Wilcoxon signed-rank test was used in **f**. Two-way ANOVA was used to compare tumor growth curves in **m,o**. Center values and error bars (**b,c,h,j,k,m,o**) indicate mean and s.e.m.

To characterize the molecular signature and functions of NDV-GP-educated SM T_{BYS} cells, we further determined differentially expressed genes (DEGs) between SM C2 and other SM clusters. A total of 1,175 and 264 DEGs were upregulated and downregulated, respectively, in C2 of SM T_{BYS} cells. Specifically, expression of genes involved in cytotoxic functions (for example, *Gzmb*, *Ccl5*, *Tbx21*) was largely
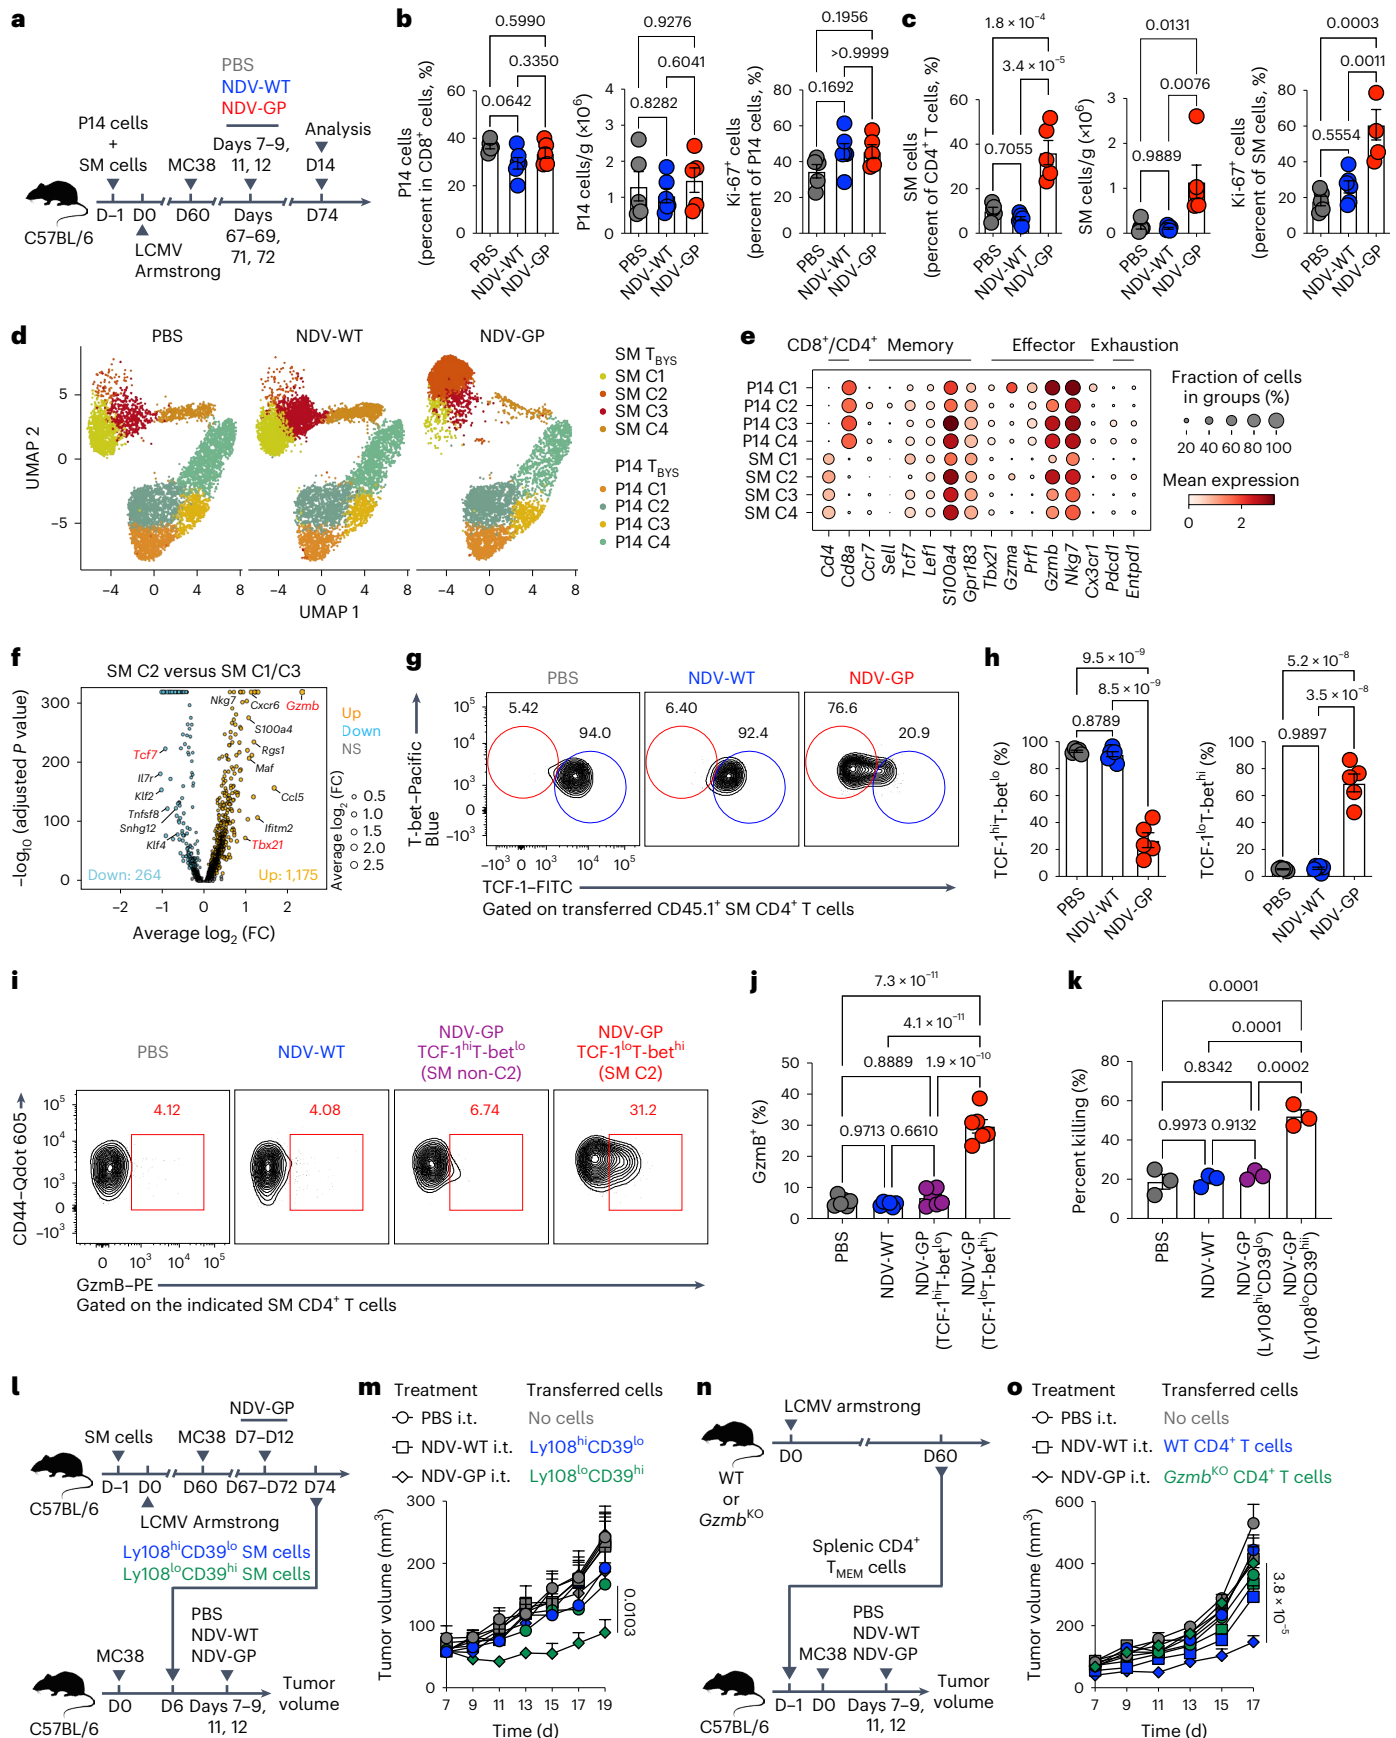

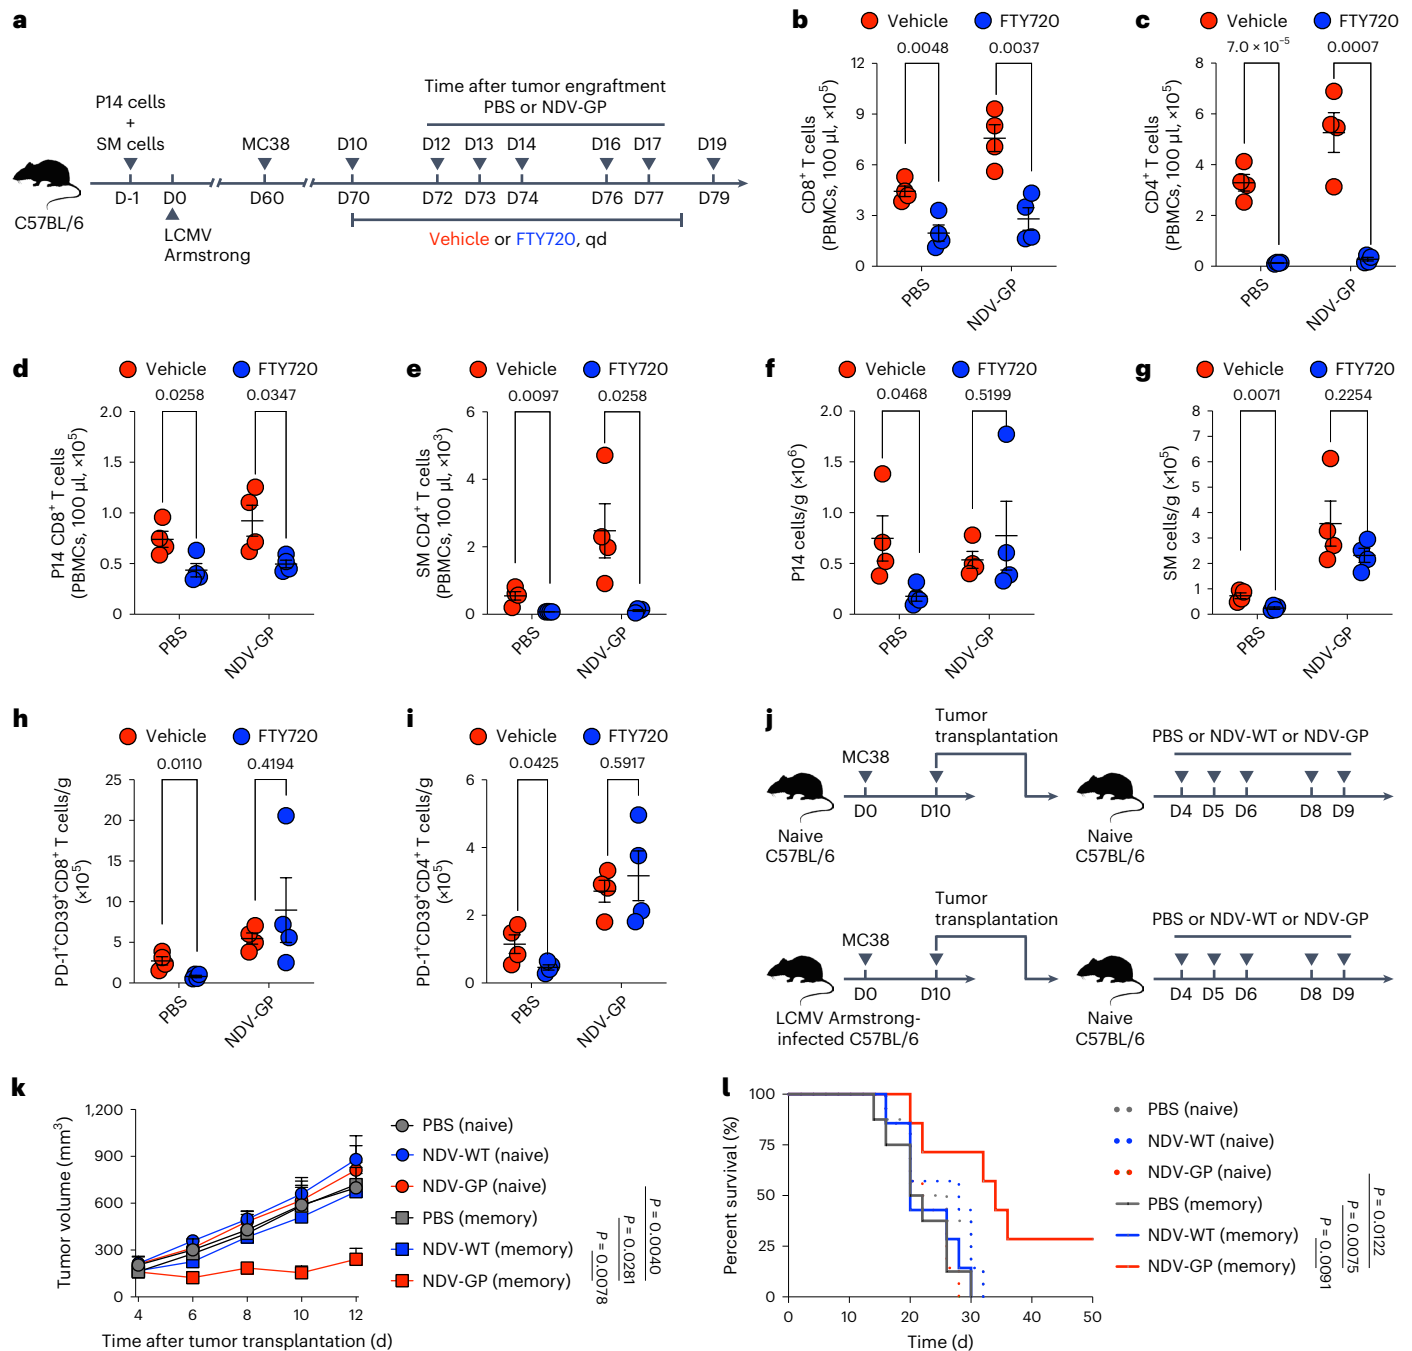

Fig. 5 | T$_{BYS}$ cells bolstered in situ by OV-BYTE therapy contribute to tumor control. a, Schematic of the experimental design. Congenic CD45.1[+] P14 CD8[+] T cells and CD45.1[+] SM CD4[+] T cells were adoptively transferred into naive C57BL/6 recipients, which were then infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On days 12, 13, 14, 16 and 17 after tumor engraftment, recipients were intratumorally treated with PBS or NDV-GP. Meanwhile, the recipients were gavaged with FTY720 drug or vehicle from day 10 to day 18. On day 19 after tumor engraftment, tumor-infiltrating T cells were analyzed. qd, quaque die. **b**–**e**, Numbers of CD8[+] T cells (**b**), CD4[+] T cells (**c**), P14 cells (**d**) and SM cells (**e**) in the peripheral blood of mice in each group as described in **a**. **f**,**g**, Numbers of tumor-infiltrating P14 T$_{BYS}$ cells (**f**) and SM T$_{BYS}$ cells (**g**). **h**,**i**, Numbers of tumor-infiltrating PD-1[+]CD39[+]CD8[+] T cells (**h**) and PD-1[+]CD39[+]CD4[+] T cells (**i**). PBS and vehicle (*n* = 4 mice), PBS and FTY720 (*n* = 4 mice), NDV-GP and vehicle (*n* = 4 mice) and NDV-GP and FTY720 (*n* = 4 mice) in **b**–**i**.**j**, Schematic of the experimental design for **k**,**l**. LCMV Armstrong-infected (day 60) or naive (uninfected) C57BL/6 mice were engrafted with MC38 cells.

On day 10 after tumor engraftment, MC38 tumors were dissected from infected or uninfected mice and transplanted to naive C57BL/6 mice, which were then intratumorally treated with PBS, NDV-WT or NDV-GP on days 4, 5, 6, 8 and 9 after tumor transplantation. **k**,**l**, Tumor growth curve (**k**) and Kaplan–Meier survival curve (**l**) of MC38 tumor mass-recipient mice treated with PBS (*n* = 5 (naive in **k**), *n* = 8 (naive in **l**), *n* = 8 (memory in **k**) or *n* = 8 (memory in **l**) mice), NDV-WT (*n* = 5 (naive in **k**), *n* = 8 (naive in **l**), *n* = 7 (memory in **k**) or *n* = 7 (memory in **l**) mice) or NDV-GP (*n* = 7 (naive in **k**), *n* = 7 (naive in **l**), *n* = 6 (memory in **k**) or *n* = 7 (memory in **l**) mice) as described in **j**. 'Naive' indicates mice transplanted with MC38 tumors originating from uninfected mice; 'memory' indicates mice transplanted with MC38 tumors originating from LCMV Armstrong-infected mice. All data are representative of two independent experiments. Two-tailed unpaired Student's *t*-test was used in **b**–**i**. The log-rank (Mantel–Cox) test was performed to compare survival curves among groups in **k**. Two-way ANOVA was used to compare tumor growth curves in **l**. Center values and error bars (**b**–**i**,**k**) indicate mean and s.e.m.

enhanced in SM C2, while expression of genes regulating T cell memory such as *Tcf7*, *Il7r* and *Klf2* was decreased (Fig. 4f). Further gene ontology analysis of SM C2 showed significant enrichment of terms related to regulation of T cell activation and regulation of the immune effector process (Extended Data Fig. 6e), indicative of active effector functions of NDV-GP-educated SM T_{BYS} C2 cells. Furthermore, by virtue of flow cytometry, we confirmed the presence of NDV-GP treatment-induced SM C2 cells as the TCF-1^{lo}T-bet^{hi} SM T_{BYS} subset (Fig. 4g,h), highly expressing granzyme B (GzmB), which was consistent with transcription profiles of SM C2 cells (Fig. 4i,j). Moreover, NDV-GP-educated SM T_{BYS} cells still preserved T_H1 cell identity as indicated by the abundance of Ly6C and the absence of CXCR5 (Extended Data Fig. 7a–c). These findings suggest that a noticeable memory-to-effector transition is involved in the CD4$^+$ T_{BYS} cell response to the OV carrying cognate epitopes.

To further investigate the potential cytotoxic functions of NDV-GP-educated TCF-1^{lo}T-bet^{hi}CD4$^+$ T_{BYS} cells, we performed ex vivo killing assays with TCF-1^{lo}T-bet^{hi} and TCF-1^{hi}T-bet^{lo} SM T_{BYS} cells from the NDV-GP-treated group as well as SM T_{BYS} cells from PBS- or NDV-WT-treated groups. Here, Ly108 and CD39 were used as surrogate surface markers to distinguish and isolate TCF-1^{lo}T-bet^{hi} (Ly108^{lo}CD39^{hi}) and TCF-1^{hi}T-bet^{lo} (Ly108^{hi}CD39^{lo}) SM T_{BYS} cells (Extended Data Fig. 7d,e). We found that NDV-GP-educated TCF-1^{lo}T-bet^{hi} (Ly108^{lo}CD39^{hi}) SM T_{BYS} cells were more efficient at directly killing target cells than TCF-1^{hi}T-bet^{lo} (Ly108^{hi}CD39^{lo}) SM T_{BYS} cells from the NDV-GP group and other control SM T_{BYS} cells from the PBS or NDV-WT group (Fig. 4k), indicating superior cytotoxic functions of NDV-GP-educated TCF-1^{lo}T-bet^{hi} SM T_{BYS} cells. To more directly evaluate the reliance on TCF-1^{lo}T-bet^{hi}CD4$^+$ T_{BYS} cells for the therapeutic effects of the OV-BYTE strategy, TCF-1^{lo}T-bet^{hi} (Ly108^{lo}CD39^{hi}) or TCF-1^{hi}T-bet^{lo} (Ly108^{hi}CD39^{lo}) SM T_{BYS} cells from NDV-GP-administered MC38 tumors were adoptively transferred into MC38 tumor-engrafted recipients with no exposure to LCMV Armstrong infection, and then these recipients were intratumorally administered PBS, NDV-WT or NDV-GP (Fig. 4l). Indeed, only transfer of the TCF-1^{lo}T-bet^{hi} SM T_{BYS} subset, but not transfer of TCF-1^{hi}T-bet^{lo} SM T_{BYS} cells, could mediate the anti-tumor effect of NDV-GP treatment (Fig. 4m).

It is well known that GzmB is important for the cytotoxicity of cytotoxic T cells[37]. Here, we also found that GzmB was specifically expressed in NDV-GP-induced cytotoxic TCF-1^{lo}T-bet^{hi} T_{BYS} cells (Fig. 4f,i,j); however, whether GzmB expression is a prerequisite for the cytotoxicity of these TCF-1^{lo}T-bet^{hi} T_{BYS} cells remains unknown. To this end, LCMV-specific memory CD4$^+$ T cells were isolated from WT C57BL/6 mice or GzmB-deficient (*Gzmb*^{KO}) mice on day 60 after infection and then transferred into naive C57BL/6 recipients as CD4$^+$ T_{BYS} cells. These recipients were then engrafted with MC38 cells and intratumorally treated with PBS, NDV-WT or NDV-GP (Fig. 4n and Extended Data Fig. 7f,g). Consistently, transfer of WT LCMV-specific memory CD4$^+$ T cells potentiated the anti-tumor function of NDV-GP administration in recipients without LCMV Armstrong exposure. Nevertheless, such protection was completely abolished in the absence of GzmB expression in CD4$^+$ T cells (Fig. 4o). In aggregate, these results highlight the GzmB-dependent cytotoxicity of CD4$^+$ T_{BYS} cells as indispensable in achieving therapeutic outcome of OV-BYTE therapy.

OV-BYTE promotes in situ T_{BYS} cells to restrain tumor growth

Reportedly, T_{TST} cells in the tumor-draining lymph node (dLN) serve as a reservoir for their counterparts in the TME that are maintained by continuous migration[19,38], which calls into question whether OV-BYTE relies on dLN egressing or TME-resident T_{BYS} cells for its anti-tumor efficacy. To this end, naive C57BL/6 mice with adoptive transfer of P14 and SM cells were infected with LCMV Armstrong and then engrafted with MC38 cells on day 60 after infection. On day 10 after tumor incubation, mice were gavaged with the sphingosine-1-phosphate receptor agonist FTY720 (ref. 39) to block dLN egress and then intratumorally

administered PBS or NDV-GP. As a control, MC38-bearing mice gavaged with PBS vehicle were intratumorally administered PBS or NDV-GP (Fig. 5a). As shown, FTY720 treatment blunted the numbers of CD8$^+$ T cells, CD4$^+$ T cells, P14 cells and SM cells in the peripheral blood of mice intratumorally administered PBS or NDV-GP (Fig. 5b–e). In addition, FTY720 treatment yielded reductions of both P14 and SM T_{BYS} cells in mice intratumorally administered PBS (Fig. 5f,g), suggesting that the migration of T_{MEM} cells from dLNs is likely necessary to sustain T_{BYS} cells in the TME. Remarkably, we observed that the FTY720-mediated decrease of P14 and SM T_{BYS} cells in the TME was almost completely rescued by intratumoral administration of NDV-GP (Fig. 5f,g), indicating that NDV-GP treatment can efficiently expand in situ virus-specific T_{BYS} cells even if the replenishment of these cells from dLNs were disrupted. Importantly, we further observed that the FTY720-mediated decrease in PD-1$^+$CD39$^+$ T cells[12,40] was also rectified by NDV-GP treatment (Fig. 5h,i), which might be due to enhanced antigen presentation upon NDV-GP treatment (Extended Data Fig. 4e,f) that optimizes T cell responses in the TME.

To further interrogate whether the in situ amplified T_{BYS} cells were responsible for OV-BYTE therapeutic efficacy, naive and LCMV Armstrong-infected C57BL/6 mice were engrafted with MC38 cells. On day 10 after tumor engraftment, MC38 tumor masses were dissected from naive or infected mice and subcutaneously transplanted to naive C57BL/6 recipients, which were then intratumorally administered PBS, NDV-WT or NDV-GP (Fig. 5j). We found that NDV-GP administration better controlled the growth of transplanted MC38 tumors with pre-existing LCMV GP-specific T cells in the tumor mass and prolonged the survival of mice transplanted with such tumors (Fig. 5k,l), mirroring the long-term protection afforded by NDV-GP in MC38 tumor-engrafted mice with LCMV Armstrong infection (Fig. 2a–c). Hence, in situ amplified virus-specific T_{BYS} cells primarily contribute to the therapeutic effects of OV-BYTE therapy.

OV-BYTE augments T_{TST} cells by inducing epitope spreading

Next, we aimed to evaluate intrinsic T_{TST} cell responses upon OV-BYTE therapy. To this end, we first investigated changes of the T cell receptor (TCR) repertoire in PD-1$^+$CD39$^+$CD8$^+$ T cells originating from PBS-, NDV-WT- or NDV-GP-treated MC38 tumors engrafted on LCMV-infected mice by performing single-cell TCR sequencing (scTCR-seq) analysis (Fig. 6a). The results revealed enhanced oligoclonal expansion of tumor-reactive CD8$^+$ T cells of the NDV-GP group in relation to those of the PBS or NDV-WT groups (Fig. 6b), suggesting potential T cell epitope spreading of tumor-reactive CD8$^+$ T cells in the presence of OV-BYTE therapy. Further examination of endogenous CD8$^+$ T cells specific to the MC38 tumor antigen p15E by both tetramer staining and a relevant peptide stimulation assay highlighted the reinforced p15E-specific CD8$^+$ T cell response, including both quantity and quality, upon NDV-GP treatment (Fig. 6c–f). Moreover, in-depth TCR repertoire analysis indicated that p15E-specific CD8$^+$ T cells from the NDV-GP group exhibited TCR clones of greater breadth and diversity than their counterparts from PBS or NDV-WT groups (Fig. 6g), further corroborating the notion that OV-BYTE therapy targeting virus-specific epitopes virtually led to epitope spreading of tumor-specific antigens and, as a result, enhanced T_{TST} cell responses.

For further proof of the anti-tumor effects caused by OV-BYTE-driven TCR epitope spreading, we inoculated C57BL/6 naive mice or those with LCMV memory with a 50:50 mix of PBS-treated and Ad5-GP-treated MC38 cells. As controls, C57BL/6 naive mice or those with LCMV memory were inoculated with the same amount of PBS-, Ad5-WT- or Ad5-GP-treated MC38 cells as well as a 50:50 mix of PBS- and Ad5-WT-treated ones (Fig. 6h). It transpired that the tumor growth of Ad5-GP-treated MC38 cells was significantly inhibited in mice with LCMV memory but not in naive mice. Also, such tumor growth inhibition was also preserved in the setting of the mixed PBS- and Ad5-GP-treated MC38 cells engrafted in mice with LCMV
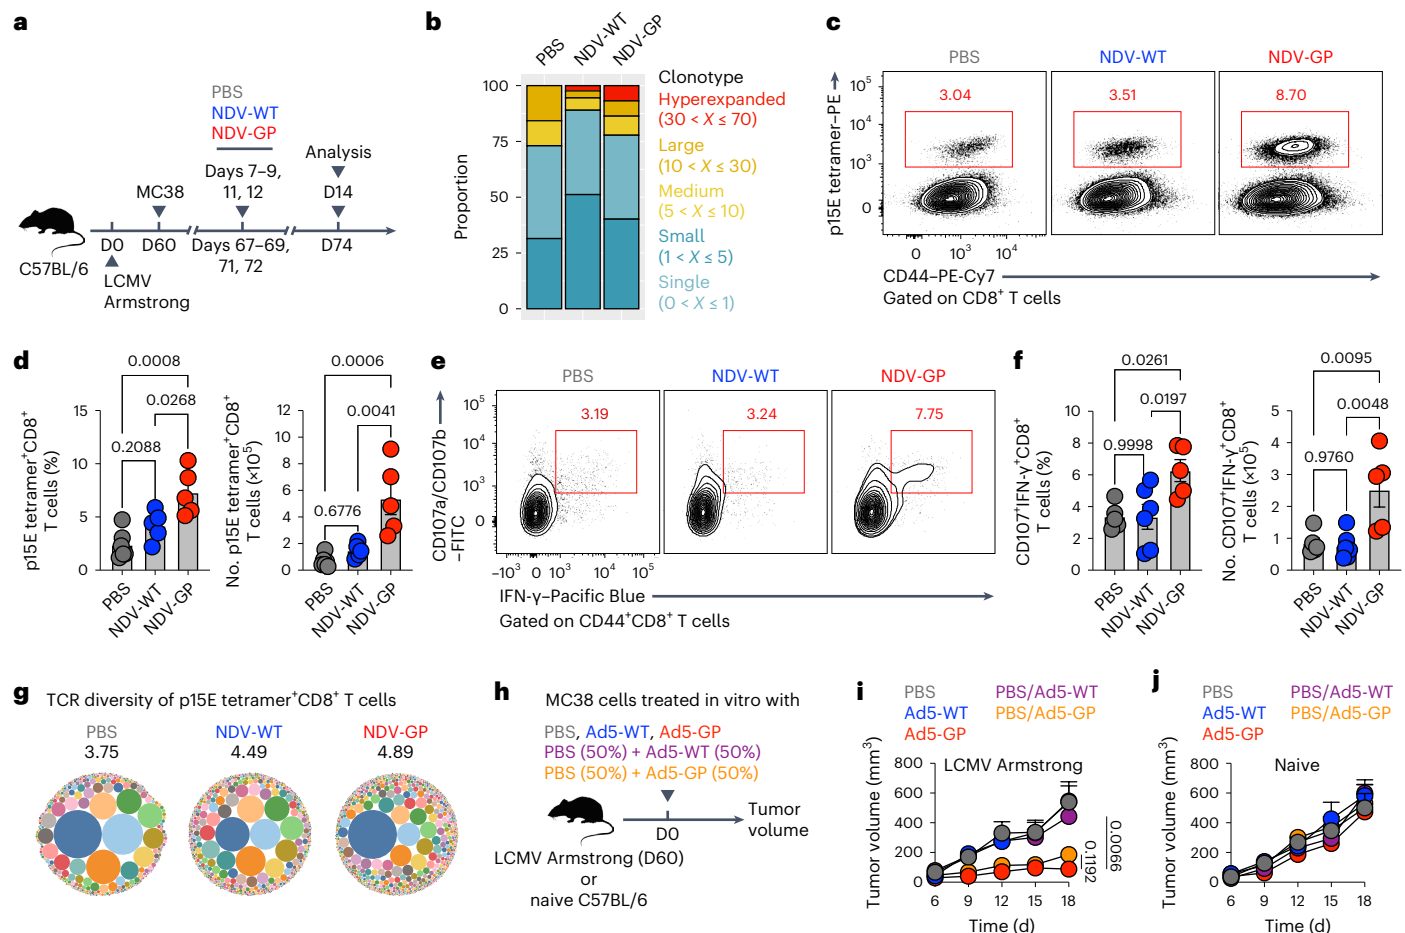

Fig. 6 | OV-BYTE therapy triggers T$_{TST}$ cell responses by inducing T cell epitope spreading. a, Schematic of the experimental design. Naive C57BL/6 mice were infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On days 7, 8, 9, 11 and 12 after tumor engraftment, MC38 tumor-engrafted mice were intratumorally treated with PBS, NDV-WT or NDV-GP. On day 14 after tumor engraftment, tumor-infiltrating T cell responses were analyzed. **b**, Frequencies of TCR clonotypes in PD-1$^+$CD39$^+$ tumor-reactive CD8$^+$ T cells originating from PBS (n = 3,222 cells), NDV-WT (n = 966 cells) or NDV-GP (n = 1,565 cells)-treated MC38 tumors on day 14 after tumor engraftment as indicated in **a**. These TCR clonotypes were divided into five groups of different sizes, including hyperexpanded ($30 < X \le 70$), large ($10 < X \le 30$), medium ($5 < X \le 10$), small ($1 < X \le 5$) and single ($0 < X \le 1$). **c**, Flow cytometry analysis of MC38 tumor-infiltrating CD44$^+$CD8$^+$ T cells from the PBS-, NDV-WT- or NDV-GP-treated group on day 14 after tumor engraftment as indicated in **a**. PBS (n = 6 mice), NDV-WT (n = 5 mice) and NDV-GP (n = 5 mice). **e**, Flow cytometry analysis of tumor-infiltrating CD44$^+$CD8$^+$ T cells (under the condition of p15E peptide stimulation) from the PBS-, NDV-WT- or NDV-GP-treated group on day 14 after tumor engraftment as indicated in **a**. Numbers adjacent to the outlined

areas indicate frequencies of IFN-γ$^+$CD107$^+$ cells of tumor-infiltrating CD44$^+$CD8$^+$ T cells. **f**, Frequency and number of tumor-infiltrating p15E peptide-stimulated IFN-γ$^+$CD107$^+$CD8$^+$ T cells in **e**. PBS (n = 5 mice), NDV-WT (n = 6 mice) and NDV-GP (n = 5 mice). **g**, Bubble charts showing Shannon entropy analysis of TCR diversity in tumor-infiltrating p15E tetramer$^+$CD39^{hi}CD8$^+$ T cells from the PBS-, NDV-WT- or NDV-GP-treated group on day 14 after tumor engraftment as indicated in **a**. **h**, Schematic of the experimental design. MC38 cells were treated in vitro with PBS, Ad5-WT (multiplicity of infection of 1) or Ad5-GP (multiplicity of infection of 1) for 48 h. Next, naive or LCMV Armstrong-infected C57BL/6 mice were inoculated with the same amount of PBS-, Ad5-WT- or Ad5-GP-treated MC38 cells or a 50:50 mix of PBS- and Ad5-GP-treated MC38 cells or a 50:50 mix of PBS- and Ad5-WT-treated MC38 cells. **i,j**, Tumor growth curves of the MC38 cells described in **h** engrafted in LCMV Armstrong-infected C57BL/6 mice (**i**) or naive C57BL/6 mice (**j**). PBS (n = 6 mice), Ad5-WT (n = 6 mice), Ad5-GP (n = 4 mice), PBS and Ad5-WT (n = 5 mice) and PBS and Ad5-GP (n = 4 mice) in **i**; PBS (n = 6 mice), Ad5-WT (n = 6 mice), Ad5-GP (n = 5 mice), PBS and Ad5-WT (n = 4 mice) and PBS and Ad5-GP (n = 6 mice) in **j**. Data (**c**–**f,i,j**) are representative of two independent experiments. One-way ANOVA with Turkey's test was used in **d,f**. Two-way ANOVA was used to compare tumor growth curves in **i,j**. Center values and error bars (**d,f,i,j**) indicate mean and s.e.m.

memory (Fig. 6i,j), indicating the development of anti-tumor responses against tumor cells expressing no viral antigens upon OV-BYTE therapy.

To further explore the potential mechanism(s) underlying OV-BYTE therapy-driven TCR epitope spreading, mice with LCMV memory were engrafted with MC38 cells expressing ovalbumin (OVA) (hereafter referred to as MC38-OVA) and were then administered PBS, NDV-WT or NDV-GP intratumorally (Extended Data Fig. 8a). Given the amenable role of DCs in fostering TCR epitope spreading of tumor-specific T cells[41,42], we next examined the DC response in

the aforementioned experimental settings, in which we observed an enhanced DC response in NDV-GP-treated MC38-OVA tumors as compared to that in PBS- or NDV-WT-treated ones (Extended Data Fig. 8b,c). More specifically, we further accessed the presentation of OVA$_{257–264}$ peptide by MHC-I H-2K^b in DCs and found that DCs presenting OVA$_{257–264}$ peptide were increased in the NDV-GP group as compared to those in the PBS or NDV-WT group (Extended Data Fig. 8d). In addition, DCs isolated from NDV-GP-treated MC38-OVA tumors rather than PBS- or NDV-WT-treated ones were more efficient in priming the tumor-specific OT-I CD8$^+$ T cell response (Extended Data Fig. 8e,f).

In sum, these data provide evidence that OV-BYTE therapy targeting bystander viral epitopes may license DCs to enhance the presentation of spreading tumor-specific epitopes to CD8[+] T_{TST} cells.

OV-BYTE and PD-L1 ICB synergize to control tumor progression

Distinct from OV-BYTE therapy that targets T_{BYS} cells, PD-1 and/or PD-L1 ICB therapy is suggested to reinvigorate T_{EX} or T_{TST} cells[2]. As effective OV treatment has been reported to remodel the TME to favor PD-1 and/or PD-L1 ICB therapy[43], we hypothesized that OV-BYTE therapy would show a synergistic anti-tumor response with PD-1 and/or PD-L1 ICB therapy. Indeed, C57BL/6 mice with LCMV memory concurrently treated with NDV-GP and PD-L1 ICB demonstrated ~60% complete protection against MC38 tumor challenge, which was superior to treatment with NDV-GP or PD-L1 ICB therapy alone (Fig. 7a,b). To further understand how T_{BYS} and T_{TST} cells respond to the combined NDV-GP and PD-L1 ICB therapy, C57BL/6 mice with LCMV memory and adoptively transferred P14 and SM cells were engrafted with MC38-OVA cells and then administered NDV-GP and PD-L1 ICB therapy (Fig. 7c). Consistent with the aforementioned data, P14 T_{BYS} cells in MC38-OVA tumors were comparable among PBS, NDV-WT and NDV-GP groups (Fig. 7d). Meanwhile, the SM T_{BYS} cell response of NDV-GP treatment was bolstered compared to that of PBS or NDV-WT treatment (Fig. 7e). However, P14 and SM T_{BYS} cells, both of which barely expressed PD-1 (Fig. 1d,j), were minimally influenced by PD-L1 ICB therapy in all groups (Fig. 7d,e). We then examined T_{TST} cell responses by ex vivo OVA$_{257–264}$ (CD8[+] T cell epitope) or OVA$_{323–339}$ (CD4[+] T cell epitope) peptide stimulation assays. Notably, the OVA$_{257–264}$-specific CD8[+] T cell response was most enhanced by concurrent treatment with PD-L1 ICB and NDV-GP in all experimental settings, evidenced by the highest proportion and number of IFN-γ-producing CD8[+] T cells upon OVA$_{257–264}$ stimulation (Fig. 7f,g). Similarly, the OVA$_{323–339}$-specific CD4[+] T cell response in the NDV-GP and PD-L1 ICB combinatorial treatment group was also superior to that of all other groups (Fig. 7h,i). Collectively, these findings demarcate that OV-BYTE potentiates the anti-tumor efficacy of PD-L1 ICB by augmenting T_{TST} cell responses.

OV-BYTE enables anti-tumoral SARS-CoV-2-specific T_{MEM} cells

Considering that a tremendous population around the globe has been either infected with SARS-CoV-2 or immunized with COVID-19 vaccines, both of which leave behind long-term persistence of SARS-CoV-2-specific T cell memory[44], we set out to determine whether such T cell memory could be used by OV-BYTE therapy. To this end, naive BALB/c mice were prime–boost intranasally vaccinated with SARS-CoV-2 receptor-binding domain (RBD) proteins, a core part of the SARS-CoV-2 spike protein and COVID-19 vaccines[45], and thus gained CD8[+] and CD4[+] T cell memory specific to the SARS-CoV-2 RBD (Extended Data Fig. 9a,b). Next, these vaccinated mice received orthotopic injection of murine triple-negative breast cancer 4T1 cells into mammary fat pads on day 60 after vaccination and then were intratumorally treated with an NDV stain expressing SARS-CoV-2 RBD (NDV-RBD). Consistently, intratumoral administration of NDV-RBD protected against the outgrowth of 4T1 tumors in SARS-CoV-2 RBD protein-immunized mice (Fig. 8a–c), with increased SARS-CoV-2 RBD-specific CD4[+] T_{BYS} cells in the TME (Extended Data Fig. 9c–i). Furthermore, the protection against 4T1 tumors was reinforced when PD-L1 ICB was given concomitantly with NDV-RBD (Fig. 8a–c).

To further probe the clinical relevance of OV-BYTE therapy leveraging SARS-CoV-2-specific T cell memory, NCG mice were engrafted with PBMCs from convalescent HLA-A2-typed patients with COVID-19 harboring SARS-CoV-2 RBD-specific T_{MEM} cells[46] (Fig. 8d). These NCG mice were inoculated with A375 human melanoma cells and then intratumorally administered NDV-WT or NDV-RBD (Fig. 8e). Noticeably, A375 tumor growth was more restricted in the NDV-RBD-treated group than that in the NDV-WT-treated one (Fig. 8f). Recapitulating NDV treatment-upregulated MHC-I and MHC-II expression in murine tumor cells (Extended Data Fig. 4e,f), both MHC-I (HLA-A2) and MHC-II (HLA-DR) expression levels of A375 tumor cells were reinforced upon NDV treatment (Extended Data Fig. 10a–c). Furthermore, the therapeutic effects of NDV-RBD in A375 tumors engrafted in NCG mice receiving transfer of convalescent COVID-19 patient PBMCs were almost diminished upon CD8[+] or CD4[+] T cell depletion (Extended Data Fig. 10d,e). These findings indicate that both CD8[+] and CD4[+] T cells contribute to the anti-tumor functions of OV-BYTE therapy using SARS-CoV-2-specific T cell memory in the humanized NCG model. We next used replication-deficient Ad5 virus expressing SARS-CoV-2 RBD (Ad5-RBD) to treat A375 tumors inoculated in NCG mice reconstructed by convalescent COVID-19 patient PBMCs (Fig. 8g). Consistently, Ad5-RBD delayed A375 tumor growth as compared to Ad5-WT (Fig. 8h). Therefore, these results together indicate that SARS-CoV-2-specific T cell memory established by infection or vaccination could be exploited by the OV-BYTE strategy to treat cancer.

Discussion

In this study, we provided a proof of concept that redirecting the antigen specificity of tumor cells to tumor-infiltrating CD8[+] and CD4[+] T_{BYS} cells effectively controls tumor progression. This therapy, called OV-BYTE, was proven to curtail tumor growth and show synergistic effects with PD-L1 ICB therapy in multiple preclinical tumor models.

Fig. 7 | OV-BYTE therapy and PD-L1 ICB therapy synergize to control tumor progression. a, Schematic of the experimental design for **b**. Naive C57BL/6 mice were infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On days 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally administered PBS, NDV-WT or NDV-GP. Meanwhile, recipients of each group were administered anti-PD-L1 blocking antibody (αPD-L1) or control immunoglobulin G (IgG) antibody on days 10, 13 and 16 after tumor engraftment. **b**, Kaplan–Meier survival curve for **a**. PBS and control (n = 11 mice), PBS and anti-PD-L1 antibody (n = 11 mice), NDV-WT and control (n = 8 mice), NDV-WT and anti-PD-L1 antibody (n = 12 mice), NDV-GP and control (n = 9 mice) and NDV-GP and anti-PD-L1 antibody (n = 8 mice). **c**, Schematic of the experimental design. Congenic CD45.1[+] P14 CD8[+] T cells and CD45.1[+] SM CD4[+] T cells were adoptively transferred into naive C57BL/6 recipients, which were then infected with LCMV Armstrong and engrafted with MC38-OVA cells on day 60 after infection. On days 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally treated with PBS, NDV-WT or NDV-GP. Meanwhile, recipients were treated with anti-PD-L1 antibody or control IgG antibody on days 10, 13 and 16 after tumor engraftment. On day 18 after tumor engraftment, tumor-infiltrating T cells were analyzed. **d,e**, Frequencies and numbers of P14 T_{BYS} cells of tumor-infiltrating CD8[+] T cells (**d**) and SM T_{BYS} cells of tumor-infiltrating CD4[+] T cells (**e**) from each group described in **c**. PBS and control (n = 4 mice), PBS and anti-PD-L1 antibody (n = 3 mice),

NDV-WT and control (n = 4 mice), NDV-WT and anti-PD-L1 antibody (n = 3 mice), NDV-GP and control (n = 3 mice) and NDV-GP and anti-PD-L1 antibody (n = 3 mice) in **d,e**. **f**, Flow cytometry analysis of tumor-infiltrating endogenous CD45.2[+]CD44[+]CD8[+] T cells. Numbers adjacent to outlined areas indicate percentages of IFN-γ[+] cells of CD45.2[+]CD44[+]CD8[+] T cells under the condition of ex vivo OVA$_{257–264}$ stimulation. **g**, Frequencies and numbers of OVA$_{257–264}$-stimulated IFN-γ[+]CD8[+] T cells. PBS and control (n = 4 mice), PBS and anti-PD-L1 antibody (n = 3 mice), NDV-WT and control (n = 4 mice), NDV-WT and anti-PD-L1 antibody (n = 3 mice), NDV-GP and control (n = 3 mice) and NDV-GP and anti-PD-L1 antibody (n = 3 mice) in **g**. **h**, Flow cytometry analysis of tumor-infiltrating endogenous CD45.2[+]CD44[+]CD4[+] T cells. Numbers adjacent to outlined areas indicate percentages of IFN-γ[+] cells of CD45.2[+]CD44[+]CD4[+] T cells under the condition of ex vivo OVA$_{323–339}$ stimulation. **i**, Frequencies and numbers of OVA$_{323–339}$-stimulated IFN-γ[+]CD4[+] T cells. PBS and control (n = 4 mice), PBS and anti-PD-L1 antibody (n = 3 mice), NDV-WT and control (n = 4 mice), NDV-WT and anti-PD-L1 antibody (n = 3 mice), NDV-GP and control (n = 3 mice) and NDV-GP and anti-PD-L1 antibody (n = 3 mice) in **i**. All data are representative of two independent experiments. The log-rank (Mantel–Cox) test was performed to compare survival curves among groups in **b**. Two-tailed unpaired Student's t-test was used in **d,e,g,i**. Center value and error bars (**d,e,g,i**) indicate mean and s.e.m.

In particular, we identified that TCF-1^{lo}T-bet^{hi} cytotoxic CD4$^+$ T$_{BYS}$ cells conveyed GzmB-dependent cytotoxicity and were amenable to OV-BYTE-mediated therapeutic effects, thus being aligned with the recently highlighted cytotoxic functions of CD4$^+$ T cells in eliminating cancer cells[47] and virus-infected cells[48].

We also provided key proof-of-concept data illustrating that OV-BYTE therapy can effectively harness SARS-CoV-2-specific T cell memory to treat cancers in preclinical models. Notably, several SARS-CoV-2-infected patients with cancer have been reported to achieve partial or complete tumor remission[49,50]. Based on our findings, we speculate that SARS-CoV-2 infection of tumor cells[51,52] in these patients may redirect these malignant cells toward the cytotoxicity of SARS-CoV-2-specific T$_{BYS}$ cells. Further clinical trials are urgently needed to validate the therapeutic efficacies of OV-BYTE therapy in patients with cancer and SARS-CoV-2-specific T cell memory.

In conclusion, we revealed that OV-BYTE therapy redirects the cytotoxicity of functional T$_{BYS}$ cells toward tumor cells for improved tumor control and has synergistic effects with PD-L1 ICB. Hence, the
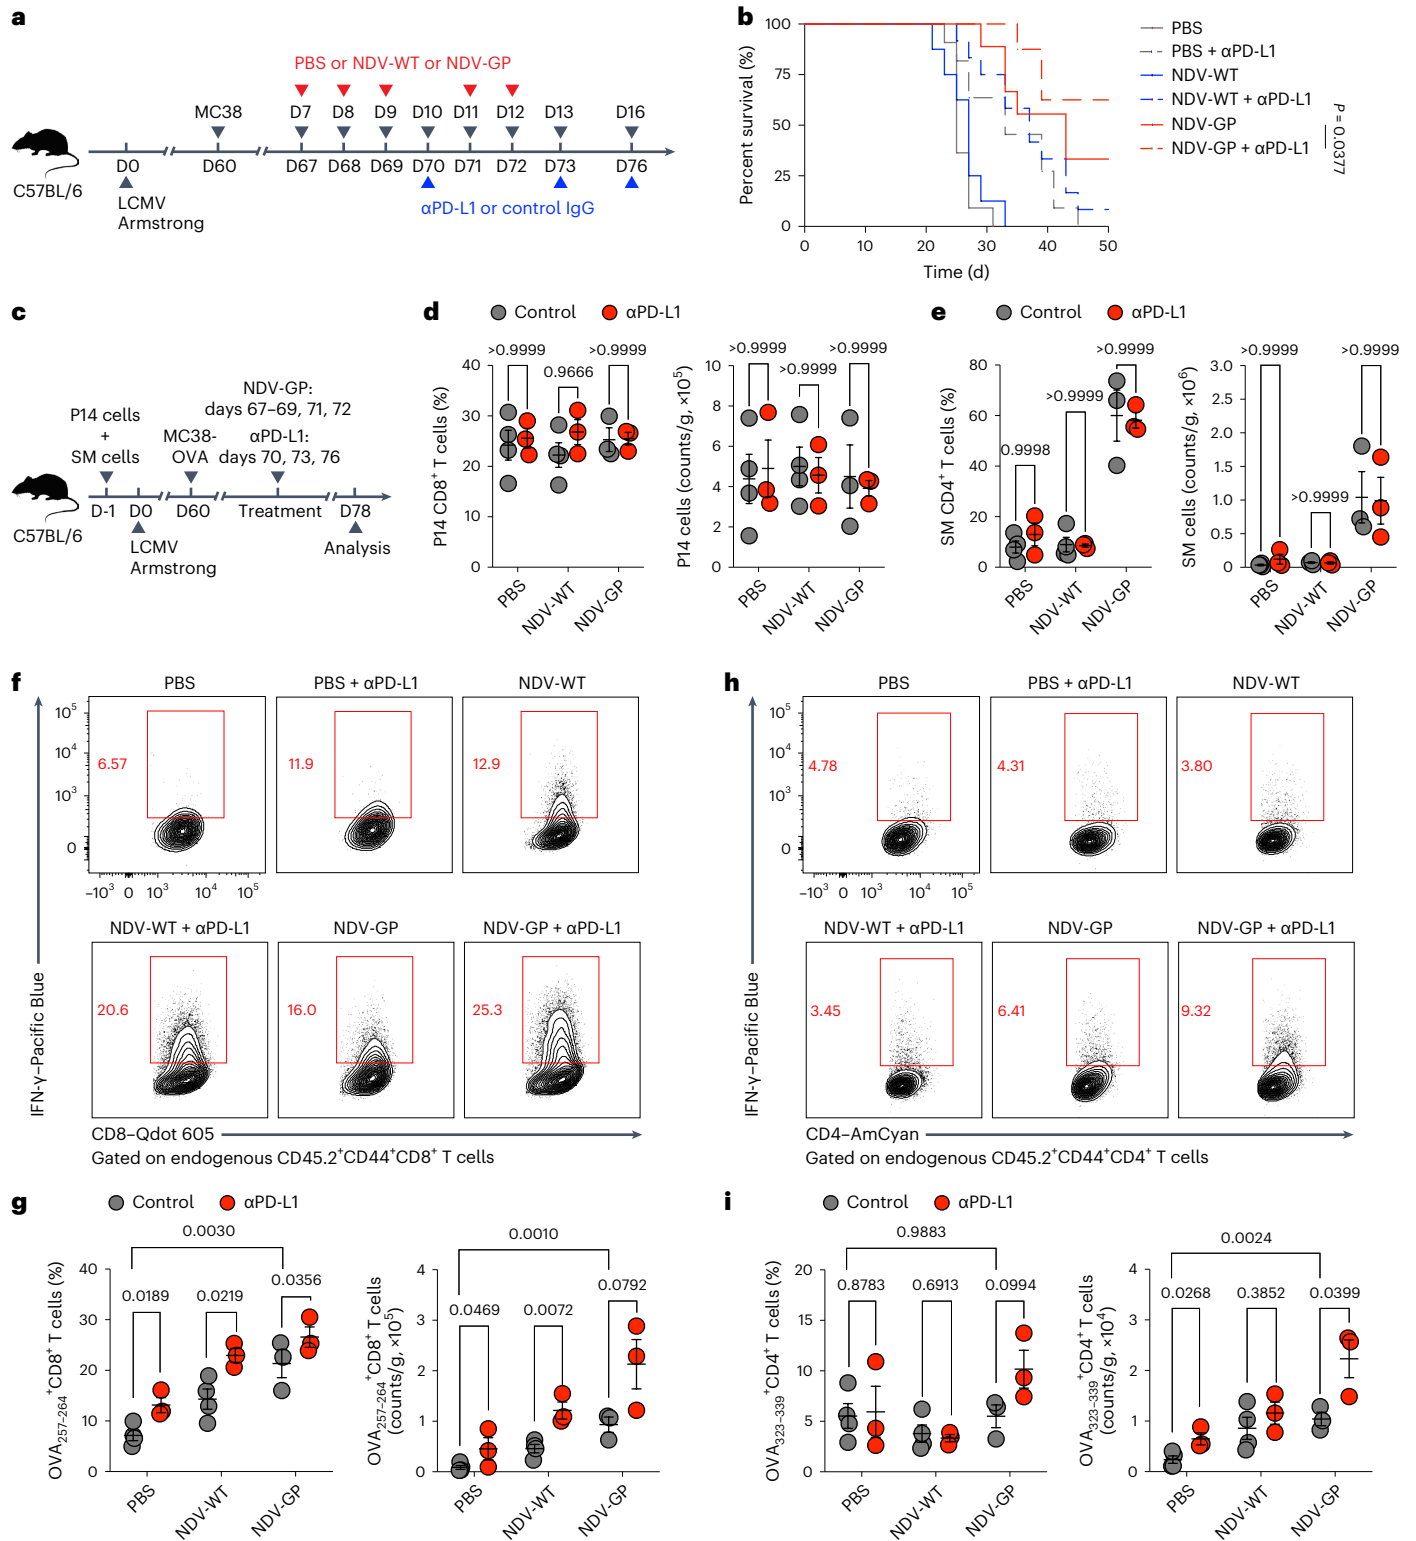

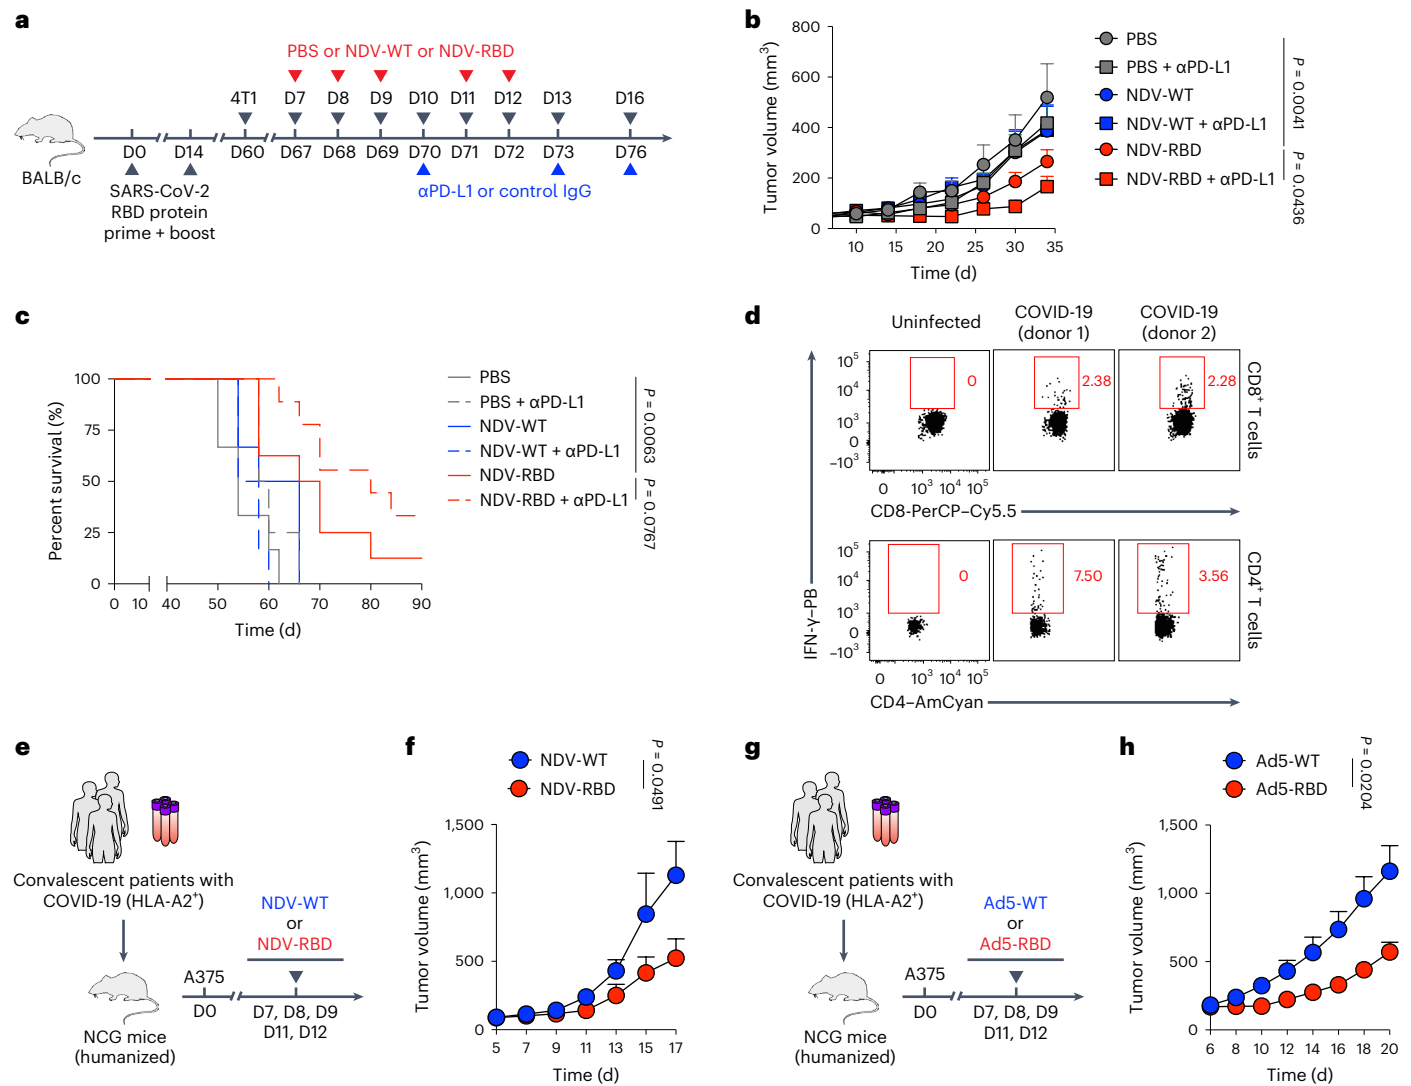

Fig. 8 | OV-BYTE therapy potentiates anti-tumor activities of SARS-CoV-2-specific T$_{MEM}$ cells. a, Schematic of the experimental design for **b**. Naive BALB/c mice were prime–boost immunized with SARS-CoV-2 RBD protein at an interval of 14 days and engrafted with 4T1 cells on day 60 after prime immunization. On days 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally administered PBS, NDV-WT or NDV-RBD. Meanwhile, recipients of each group were administered anti-PD-L1 blocking antibody or control IgG antibody on days 10, 13 and 16 after tumor engraftment. **b,c**, Tumor growth curve (**b**) and Kaplan–Meier survival curve (**c**) from **a**. combination of OV-BYTE and PD-1 and/or PD-L1 ICB might expand the toolkits for cancer immunotherapy.

Methods

Research involving animal experiments with all relevant ethical regulations is detailed in Mice below. Research involving human samples with all relevant ethical regulations is detailed in Human participants and the humanized mouse model below.

Mice

C57BL/6, BALB/c, OT-I and CD45.1$^+$ (B6.SJL-*Ptprc^a Pepc^b*/BoyJ) mice were purchased from the Jackson Laboratories. P14 and SM mice were gifts from R. Ahmed (Emory University). CXCR5−GFP knockin mice were generated by inserting an IRES-GFP construct after the open reading frame of *Cxcr5* (ref. 53). *Gzmb*^{KO} mice were provided by F. Shao (Chinese Academy of Medical Sciences and National Institute of Biological Sciences). All experiments involving C57BL/6, BALB/c, P14, SM, OT-I,

CXCR5–GFP knockin, CD45.1[+] and *Gzmb*[KO] mice were carried out in accordance with procedures approved by the Institutional Animal Care and Use Committees of the Third Military Medical University. Immunodeficient NOD/ShiLtJGpt-*Prkdc*[em26Cd52]*Il2rg*[em26Cd22]/Gpt (NCG) mice were purchased from GemPharmatech. All experiments involving the generation and characterization of humanized NCG mice were approved by an institutional animal care and use committee at the Model Animal Research Center at Nanjing University (AP LY-01). All mice used for animal experiments were 6–10 weeks of age, and both sexes were included in the study, except only female BALB/c mice were used for the engraftment of 4T1 breast cancer cells. All mice were housed under specific-pathogen free conditions with normal mouse chow (Jiangsu Xietong Shengwu), a 12-h light–12-h dark cycle and controlled temperature (20–22 °C) and humidity (40–60%).

Viral infection and protein immunization
To establish LCMV Armstrong infection, naive C57BL/6 mice were injected intraperitoneally with 2×10^5 plaque-forming units (PFU) of LCMV Armstrong. To establish SARS-CoV-2-specific T cell memory, naive BALB/c mice were intranasally immunized with two doses of 10 μg SARS-CoV-2 RBD protein–mFC tag (Sino Biological, 40592-V05H) conjugated to 10 μg CpG ODN 1826 (Invitrogen, tlrl-1826) at an interval of 14 d.

Construction of modified oncolytic viruses
NDV-LCMV GP, NDV-LCMV NP, NDV-SARS-CoV-2 RBD and NDV-H1N1 NP were generated as previously described[54]; specifically, the full-length NDV SG10 cDNA clone, pOK-SG10, was used as the backbone to construct a recombinant cDNA clone containing the gene sequences encoding LCMV GP, LCMV NP, SARS-CoV-2 RBD or H1N1 NP between the P and M genes. Ad5-GP and Ad5-RBD were generated by inserting the gene sequences encoding LCMV GP protein and SARS-CoV-2 RBD protein, respectively, into Ad5 lacking 24 base pairs encoding eight amino acids in the pRb-binding domain of E1A and E3.

Tumor models
MC38 (NM-S13) and MC38-OVA (NM-S13-TM56) cells were purchased from the Shanghai Model Organisms Center. B16F10 (CRL-6475), 4T1 (CRL-2539) and A375 (CRL-1619) cells were purchased from ATCC. B16-GP cells were generated by CRISPR–Cas9-mediated insertion of the LCMV GP gene into the genome of B16F10 cells. All tumor cell lines were cultured in complete DMEM-10 medium (Gibco) supplied with 10% FBS (Gibco), 1% penicillin–streptomycin (Gibco) and 1% L-glutamine (Gibco). For subcutaneous tumor models, C57BL/6 mice were implanted with $3–5 \times 10^5$ MC38, MC38-OVA, B16F10 or B16-GP cells in the left flank of leg. For the mouse breast cancer model, 2×10^5 4T1 cells were implanted into the mammary fat pad of female BALB/c mice. Tumor volumes were determined in two dimensions with a caliper and calculated according to the formula $((\text{length} \times \text{width}^2)/2)$. For the NICD and AKT plasmid-induced intrahepatic cholangiocarcinoma model, the hydrodynamic tail vein of C57BL/6 mice was injected with a mixture of the three plasmids, including Myc-tagged NICD1 (10 μg per mouse), Myc-tagged AKT (4 μg per mouse) and SB100 (1 μg per mouse), according to a published study[35]. For the tumor transplantation model, MC38 tumors were surgically dissected from donor mice and cut into pieces of about 5 mm³ in size. Next, tumor specimens were subcutaneously transplanted into the same flank of recipients. Tumor-engrafted mice were killed at the indicated time points on the premise of humane endpoints (tumor volume not exceeding 2,000 mm³).

PCR with reverse transcription
Total RNA from tumor cells was extracted by using TRIzol LS (Life Technologies) and reverse transcribed using the RevertAid Minus First Strand cDNA Synthesis Kit (Thermo Scientific, K1622) according to the manufacturer's protocol. Relative expression levels of transcripts were determined using AceQ qPCR SYBR Green Master Mix (Vazyme, Q111) with a CFX96 Touch Real-Time System (Bio-Rad). The primers used in the study are as follows: LCMV GP gene (forward, 5′-GCAACTGCTGTGTTCCCGAAAC-3′; reverse, 5′-CATTCACCTGGACTTTGTCAGACTC-3′), LCMV NP gene (forward, 5′-CTCACACGGCATGGATCTTG-3′; reverse, 5′-TCGAAGCTTCCCTGGTCATT-3′) and *Hprt1* (forward, 5′-TCAGTCAACGGGGGACATAAA-3′; reverse, 5′-GGGGCTGTACTGCTTAACCAG-3′).

Immunofluorescence
MC38 cells were transferred to 12-mm coverslips in a 12-well plate. After fixation and permeabilization, cells on coverslips were stained with DAPI (Sigma, D9542) and for actin (Cell Signaling Technology, 3134) and the NDV P protein (made in house). Images were acquired with a Zeiss LSM 510 confocal fluorescence microscope and processed with LSM Image Examiner (version 4.0).

Adoptive transfer of T cells
For the LCMV Armstrong infection model, 5×10^4 congenic naive splenic P14 cells and/or SM cells were adoptively transferred into recipients 1 d before infection. For the subcutaneous B16-GP tumor model, 5×10^5 congenic naive splenic P14 cells and/or SM cells were adoptively transferred into recipients 1 d before B16-GP tumor engraftment. For the LCMV Armstrong-specific T_{MEM} cell transfer experiment, 4×10^6 CD8[+] and/or CD4[+] T cells with LCMV memory were isolated from the spleens of infected mice at day 60 after LCMV Armstrong infection and then adoptively transferred into naive C57BL/6 recipients. For the MC38-OVA tumor model, 2×10^3 congenic OT-I cells were adoptively transferred into recipients on day 10 after MC38-OVA tumor engraftment.

Isolation of lymphocytes
Lymphocytes in spleens were collected by mashing spleens through a cell strainer (BD Falcon). Lymphocytes in the peripheral blood were obtained by using a Ficoll (TBD, LTS107701) density gradient. To obtain liver-resident lymphocytes, mice were euthanized and perfused. Next, livers were dissected and mechanically minced. Liver-resident lymphocytes were acquired using a Percoll (GE Healthcare, 17-0891-09) density gradient. To obtain MC38, MC38-OVA or 4T1 tumor-infiltrating lymphocytes (TILs), tumors were mechanically minced, digested using with 1 mg ml⁻¹ collagenase I (Sigma, c0130) and mashed through filters. Next, we enriched for TILs using a Percoll (GE Healthcare, 17-0891-09) density gradient. To collect B16F10 or B16-GP TILs, tumors were mechanically minced, and we enriched for TILs using a Percoll (GE Healthcare, 17-0891-09) density gradient.

Human participants and the humanized mouse model
We enrolled a cohort containing eight HLA-A2-positive healthy volunteers and a cohort containing four HLA-A2-positive convalescent patients with COVID-19. All volunteers provided written informed consent. The study received institutional review board approvals at Chongqing Public Health Medical Center (2020-023-01-KY). PBMCs from blood donated by these volunteers were isolated using a Ficoll (TBD, LTS107701) density gradient. NCG mice were injected intravenously with 5×10^6 human PBMCs. After the humanization rate reached an appropriate proportion, 5×10^6 A375 cells were subcutaneously injected into each side of recipient mice in a volume of 100 μl PBS. Tumors were measured every day using calipers, and the tumor volume was calculated using the following formula: $(\text{length} \times \text{width}^2)/2$.

Enzyme-linked immunosorbent assay
ELISA plates (Thermo Fisher, 446469) were coated with 50 ng H1N1 NP protein (Sino Biological, 40777-V08B) in 100 μl PBS per well overnight. Next, the ELISA plates were incubated with blocking buffer (5% FBS with

0.1% Tween-20 in PBS) for 1 h. Fifty-fold-diluted sera or blocking buffer (negative control) were next added to each well and incubated for 1 h. The ELISA plates were then washed with PBST (PBS with 0.1% Tween-20), incubated with HRP-conjugated goat anti-human IgG antibody (Bioss Biotech) and washed with PBS, and TMB was added (Beyotime). Samples were allowed to react with TMB for ~5 min, and then the reaction in ELISA plates was stopped by adding 1 M H_2SO_4 stop buffer. Optical density values were determined at 450 nm.

Administration of reagents

For administration of OVs, mice were treated intratumorally with 2×10^6 PFU of NDV or 1×10^8 PFU of Ad5 in 50 µl PBS. For the LCMV GP-neutralizing antibody experiment, sera containing LCMV GP-neutralizing antibodies were collected from C57BL/6 mice infected with LCMV Cl13 (ref. 55), pathogen inactivated and then incubated in vitro with NDV-GP. For PD-L1 ICB experiments, mice were intraperitoneally injected with 150 µg anti-PD-L1 antibody (BioXCell, clone 10F.9G2) or an isotype-matched control antibody (BioXCell, clone LTF-2) on days 10, 13 and 16 after tumor engraftment. For the depletion of $CD8^+$ or $CD4^+$ T cells in C57BL/6 mice, mice were intraperitoneally injected with 100 µg anti-CD8 antibody (BioXCell, clone 53-6.7) or 100 µg anti-CD4 antibody (BioXCell, clone GK1.5) on days −1, 1, 7 and 12 after tumor engraftment. For the depletion of $CD8^+$ or $CD4^+$ T cells in humanized NCG mice, mice were intraperitoneally injected with 200 µg anti-CD8 antibody (BioXCell, clone OKT8) or 200 µg anti-CD4 antibody (BioXCell, clone OKT4) on days −2 and 2 and then further injected intraperitoneally with 50 µg anti-CD8 antibody or anti-CD4 antibody on days 9 and 16 after tumor engraftment. For FTY720 treatment, mice were intraperitoneally injected with 0.3 mg per kg FTY720 (Merck, SML0700).

Flow cytometry

All information on antibodies for flow cytometry analysis in this study is provided in the Reporting Summary. Cell surface marker staining was performed in PBS containing 2% FBS. For the detection of cytokines, lymphocytes were stimulated for 6 h in the presence of the indicated peptide (0.2 µg ml^{-1} LCMV GP$_{33-41}$, LCMV GP$_{66-77}$, LCMV GP$_{91-101}$, LCMV GP$_{118-125}$, LCMV GP$_{276-286}$, OVA$_{257-264}$, OVA$_{323-339}$ or p15E peptide) and anti-CD107a and anti-CD107b antibodies in an incubator at 37 °C. Alternatively, lymphocytes were incubated for 6 h with 1 µg ml^{-1} of an H1N1 NP peptide pool (Miltenyi Biotec, 130-097-278), for 18 h with 1 µg ml^{-1} of a SARS-CoV-2 S1 peptide pool (Sino Biological, PP003-A) or for 44 h with 1 µM recombinant SARS-CoV-2 RBD protein in an incubator at 37 °C. Brefeldin A and monensin (BD Biosciences) were added into the culture 4 h before detection. Intracellular cytokine staining for IL-2, IFN-γ and TNF-α was performed with the Cytofix/Cytoperm Fixation/Permeabilization Kit (BD Biosciences, 554714). Staining for T-bet, TCF-1, TOX, Eomes, Ki-67 and GzmB was performed with the Foxp3/Transcription Factor Staining Buffer Set (eBioscience, 00-5523). Dead cells were stained with the LIVE/DEAD Fixable Near-IR Dead Cell Stain Kit (Life Technologies). Flow cytometry data were acquired using FACSDiva software (version 7.0) in the FACSCanto II (BD Biosciences) or the FACSFortessa (BD Biosciences) and analyzed using FlowJo (version 10.4.0). Cell sorting experiments were performed with the BD FACSAria III (BD Biosciences).

Ex vivo killing assay

In the experiment illustrating NDV-GP-mediated GP protein expression in MC38 cells, NDV-WT- and NDV-GP-infected MC38 cells were labeled with CellTrace Violet (Thermo Fisher) at 0.1 µM and 1 µM, respectively, and then mixed at a 1:1 ratio. Next, labeled MC38 cells (target) were mixed with LCMV Armstrong-activated or naive $CD8^+$ T cells (effector) at a 100:1, 50:1 or 25:1 E:T ratio and co-cultured at 37 °C for 8 h. In experiments assessing the killing efficacy of SM T_{BYS} cells, NDV-WT-treated MC38 cells were labeled with CellTrace Violet (Thermo Fisher) at either

0.1 µM or 1 µM. MC38 cells labeled with 1 µM CellTrace Violet were pulsed with 2 µg LCMV GP$_{66-77}$ peptide and then mixed with MC38 cells labeled with 0.1 µM CellTrace Violet at a 1:1 ratio. These labeled MC38 target cells were further mixed with sorted SM T_{BYS} cells or naive $CD4^+$ T cells (effector) at a 9:1 E:T ratio and co-cultured at 37 °C for 8 h. The killing efficiency was determined as follows: 100 − (((percent MC38-GP with LCMV-specific T cells)/(percent control MC38 with LCMV-specific T cells))/((percent MC38-GP with naive T cells)/(percent control MC38 with naive T cells))) × 100.

scRNA-seq library preparation, sequencing and data processing

scRNA-seq libraries were prepared using Chromium Next GEM Single Cell 3′ Reagent Kits (10x Genomics) according to the manufacturer's instructions and then sequenced with paired-end sequencing of 150 nucleotides on each end on one lane of a NovaSeq 6000 per sample. Raw gene expression matrices were generated with the Cell Ranger (version 6.1.1) pipeline coupled with the mm10 genome annotation reference, which was then processed using Seurat[56], and only cells with >1,000 detected genes or a mitochondrial read percentage <5 were retained. Doublets were automatically detected and removed by scDblFinder[57] before all samples were combined into a count matrix using the merge function in Seurat. Data were log normalized and scaled using 'NormalizeData' and 'ScaleData'. The top 2,000 most variable genes were calculated using 'FindVariableGenes' and then used in the PCA calculation with RunPCA. The number of top PCs used to calculate a UMAP dimensional reduction was decided by observation of the graphic output of the 'ElbowPlot' function.

Identification of differentially expressed genes and functional enrichment

DEG testing was performed using the 'FindMarkers' function in Seurat with default parameters. The top 200 DEGs with the highest log$_2$ (fold change) values and a maximum FDR value of 0.01 were filtered and exploited for the enrichment analysis, which was conducted using the Metascape webtool (https://www.metascape.org). Gene sets were derived from the GO Biological Process ontology.

Defining cell state scores

We generated gene sets representing the signatures of T_{CM} cells and T_{RM} cells by conducting DEG identification analysis on external bulk RNA-seq datasets[31,32]. The resulting gene sets were used as input for the 'AddModuleScore' function in Seurat to calculate the corresponding cell scores, which could be further interpreted as phenotypic similarity to T_{CM} and T_{RM} for each cell.

Consensus non-negative matrix factorization analysis

Data from P14 T_{BYS} cells (PBS group) were merged with data from P14 T_{RM} cells (kidney, liver, salivary gland, siIEL)[24] and P14 T_{MEM} cells (days 32, 60 and 90)[25] from an external dataset to generate a mixed count matrix first, which was the foundation for the inference of consensus gene programs. In detail, we executed the 'cnmf prepare' command from the cNMF package[58] to normalize the input matrix and prepare the run parameters, the 'cnmf factorize' command to factorize the matrix and the 'cnmf combine' command to combine the individual spectrum result files for each K (the expected number of gene modules, which should be previously assigned by prior knowledge in the first step) into a merged file. The optimal number for K was decided by observing the output of the 'cnmf k_selection_plot' command, considering the tradeoff between stability and error, which distinguished the number 9 from the other candidates for the optimal value of K. At the desired value of K, we obtained consensus estimates for the programs and their usages by executing the 'cnmf consensus' command. Calculation and visualization using Radviz was based solely on the results of the cNMF analysis.

RNA velocity analysis

Read annotations for sequenced samples were performed using the 'velocity run 10X' command-line tool with BAM (velocyto.py), genome annotation and repeat annotation[59]. Repeat annotation files were downloaded from the UCSC Genome Browser. The UMAP embedding matrix computed with the Seurat pipeline was used to construct the velocity map with the scVelo Python package[60]. Briefly, the total procedure involved execution of the pp.filtered_and_normalized, pp.moments, pp.neighbors, tl.recover_dynamics and tl.velocity (with the mode parameter set to 'dynamical') functions from the scVelo package.

Bulk TCR amplification, sequencing and data analysis

RNA samples were analyzed by high-throughput sequencing of the TCR β-chain (TRB) using the ImmuHub TCR profiling system[61] (ImmuQuad Biotech). The raw sequencing data were then aligned with NCBI and PCR. The resulting nucleotide and amino acid sequences of complementarity-determining region 3 (CDR3) of TRB were determined, and those with out-of-frame and stop codon sequences were removed from the identified TRB repertoire. We further defined the amount of each TRB clonotype by adding numbers of TRB clones sharing the same nucleotide sequence as CDR3. Shannon's index[62] was used to assess the diversity of TCR clones within each sample, which was defined as follows:

$$H' = -\sum p_i \ln(p_i),$$

where p_i defines the frequency of the i-th specific clonotype.

Single-cell TCR sequencing data analysis

scTCR-seq libraries were prepared using 10x Genomics 5′ Single Cell Immune Profiling technology according to the manufacturer's instructions. Sequencing was performed by using the NovaSeq 6000. TCR clonotype identification, alignment and annotation were performed using the 10x Genomics Cell Ranger pipeline (version 6.1.1) according to the manufacturer's instructions. Clonotype alignment was performed against the Cell Ranger human V(D)J reference library 3.1.0 (GRCh38 and Ensembl GTF version 94). TCR clonotypes were defined using the 'combineTCR' function in scRepertoire[63] (with the 'cloneCall' parameter set to 'CTstrict'). Clonal expansion was determined using a five-group classification. The percentage of cells in single (0–1), small (2–5 cells), medium (6–10 cells), large (11–30) and hyperexpanded (31–70 cells) clones was determined for $Pdcd1^+Entpd1^+Cd8a^+$ T cells.

Statistics and reproducibility

No statistical method was used to predetermine sample size, but our sample sizes are similar to those reported in previous publications[19,27,28,53,64]. No data were excluded from the analyses. The experiments were not randomized. The investigators were not blinded to allocation during experiments and outcome assessment. Statistical analysis was performed with Prism 9.0 (GraphPad). Normality and equal variances of data were formally tested. For comparisons between two independent groups, two-tailed unpaired Student's t-test was used. For comparisons among three or more groups, one-way ANOVA with Turkey's test was used. Two-way ANOVA was used to compare tumor growth curves. The log-rank (Mantel–Cox) test was performed to compare survival curves among groups. Graphs show individual samples, and center values indicate the mean. P values less than 0.05 were defined as statistically significant.

Reporting summary

Further information on research design is available in the Nature Portfolio Reporting Summary linked to this article.

Data availability

scRNA-seq data of T_{BYS} cells and conventional memory SM cells, scRNA-seq and scTCR-seq data of PD-1$^+$CD39$^+$CD8$^+$ T cells and TCR-seq data of p15E tetramer$^+$CD8$^+$ T cells in this study have been deposited in the Gene Expression Omnibus under accession code GSE222002. Public scRNA-seq and bulk RNA-seq data reanalyzed here are available under accession codes GSE182276, GSE131847 and GSE128197. All other data supporting the findings of this study are available from the corresponding authors upon reasonable request. Source data are provided with this paper.

Code availability

There were no custom algorithms in this study. Open-source software was used to analyze data. Details of software versions are specified in the Methods.

Extended Data Fig. 1 | Molecular characteristics of virus-specific T$_{BYS}$ cells.
a, Flow cytometry gating strategy of MC38 tumor-infiltrating P14 CD8$^+$ T$_{BYS}$ cells and SM CD4$^+$ T$_{BYS}$ cells. Congenic CD45.1$^+$ P14 CD8$^+$ T cells and CD45.1$^+$ SM CD4$^+$ T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2$^+$), which were then infected with LCMV Armstrong and inoculated with MC38 cells on day 60 after infection. On day 10, 15 and 20 after tumor engraftment, tumor-infiltrating P14 and SM cells were analyzed by flow cytometry. The leftmost flow cytometry data (FSC$^-$A/SSC-A) showed total cells in MC38 tumors, wherein lymphocytes were gated and further gated for singlets in the adjacent two flow cytometry data (FSC-H/FSC-W and SSC-H/SSC-W). Then, live cells (negative for Live/dead-dye-APC-Cy7) were gated on singlets and further gated for CD8$^+$CD44$^+$ T cells or CD4$^+$CD44$^+$ T cells. Lastly, CD45.1$^+$Vα2$^+$ P14 CD8$^+$ T cells and CD45.1$^+$Vα2$^+$ SM CD4$^+$ T cells were gated on CD8$^+$CD44$^+$ T cells or CD4$^+$CD44$^+$ T cells, respectively. **b**, Schematic graph of the experimental design. (I) P14 T$_{MEM}$ cell model: congenic CD45.1$^+$ P14 CD8$^+$ T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2$^+$), which were then infected with LCMV Armstrong. On day 70 after infection, CD45.1$^+$Vα2$^+$ P14 cells (defined as CD8$^+$ T$_{MEM}$ cells) from the spleens of LCMV Armstrong-infected recipients were analyzed. (II) P14 T$_{BYS}$ cell model: congenic CD45.1$^+$ P14 CD8$^+$ T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2$^+$), which were then infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On day 10-post tumor engraftment, CD45.1$^+$Vα2$^+$ P14 cells (defined as CD8$^+$ T$_{BYS}$ cells) from the MC38 tumors of LCMV Armstrong-infected recipients were analyzed. (III) P14 T$_{EX}$ cell model: congenic CD45.1$^+$ P14 CD8$^+$ T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2$^+$), which were then engrafted
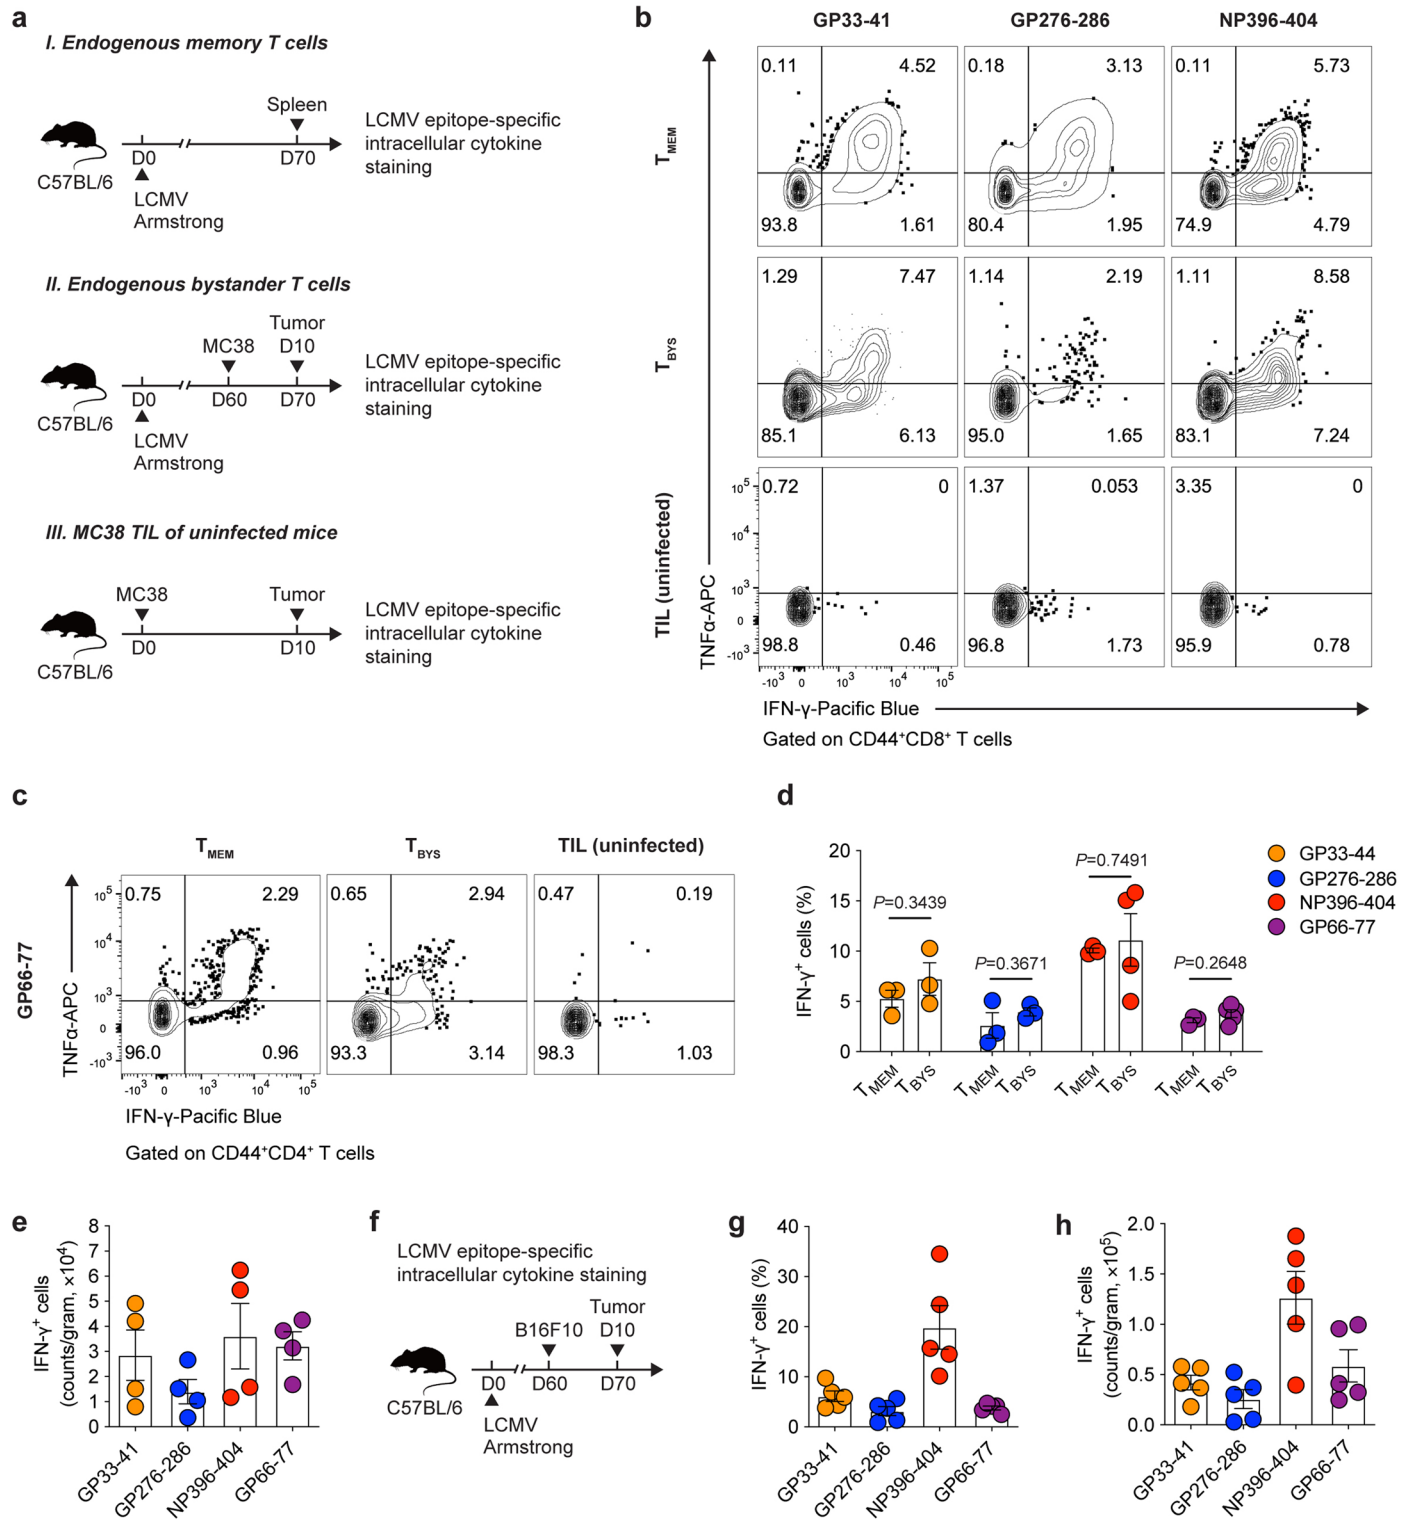

with B16-GP cells. On day 15-post tumor engraftment, CD45.1$^+$Vα2$^+$ P14 (defined as CD8$^+$ T$_{EX}$ cells) from the B16-GP tumors were analyzed. **c**, Schematic graph of the experimental design for scRNA-seq data. (I) P14 T$_{BYS}$ and SM T$_{BYS}$ cell model: congenic CD45.1$^+$ P14 CD8$^+$ T cells and CD45.1$^+$ SM CD4$^+$ T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2$^+$), which were then infected with LCMV Armstrong and engrafted with MC38 cells on day 45 after infection. On day 15-post tumor engraftment, CD45.1$^+$Vα2$^+$ P14 cells and CD45.1$^+$Vα2$^+$ SM cells were isolated from the MC38 tumors and performed with scRNA-seq library preparation. (II) P14 T$_{MEM}$ and T$_{RM}$ cell model: congenic CD45.1$^+$ P14 CD8$^+$ T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2$^+$), which were then infected with LCMV Armstrong. On day 32-post infection, CD45.1$^+$Vα2$^+$ P14 cells were isolated from the spleens, livers, kidneys, SGs and siIELs of recipients and performed with scRNA-seq library preparation. On days 60 and 90 after infection, CD45.1$^+$Vα2$^+$ P14 cells were isolated from the spleens of recipients and performed with scRNA-seq library preparation. These P14 cell datasets were exacted from the external scRNA-seq datasets (GSE182276 and GSE131847). (III) SM T$_{MEM}$ cell model: congenic CD45.1$^+$ SM CD4$^+$ T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2$^+$), which were then infected with LCMV Armstrong. On day 60 after infection, CD45.1$^+$Vα2$^+$ SM cells were isolated from the spleens of recipients and performed with scRNA-seq library preparation. **d**, tSNEs showing activities of 9 gene expression programs in P14 T$_{MEM}$, P14 T$_{RM}$ and P14 T$_{BYS}$ cells inferred by consensus non-negative matrix factorization (cNMF), with 38,880 cells in total passing quality control. **e**, Heatmap showing the top 10 differential expressed genes in each program in d.
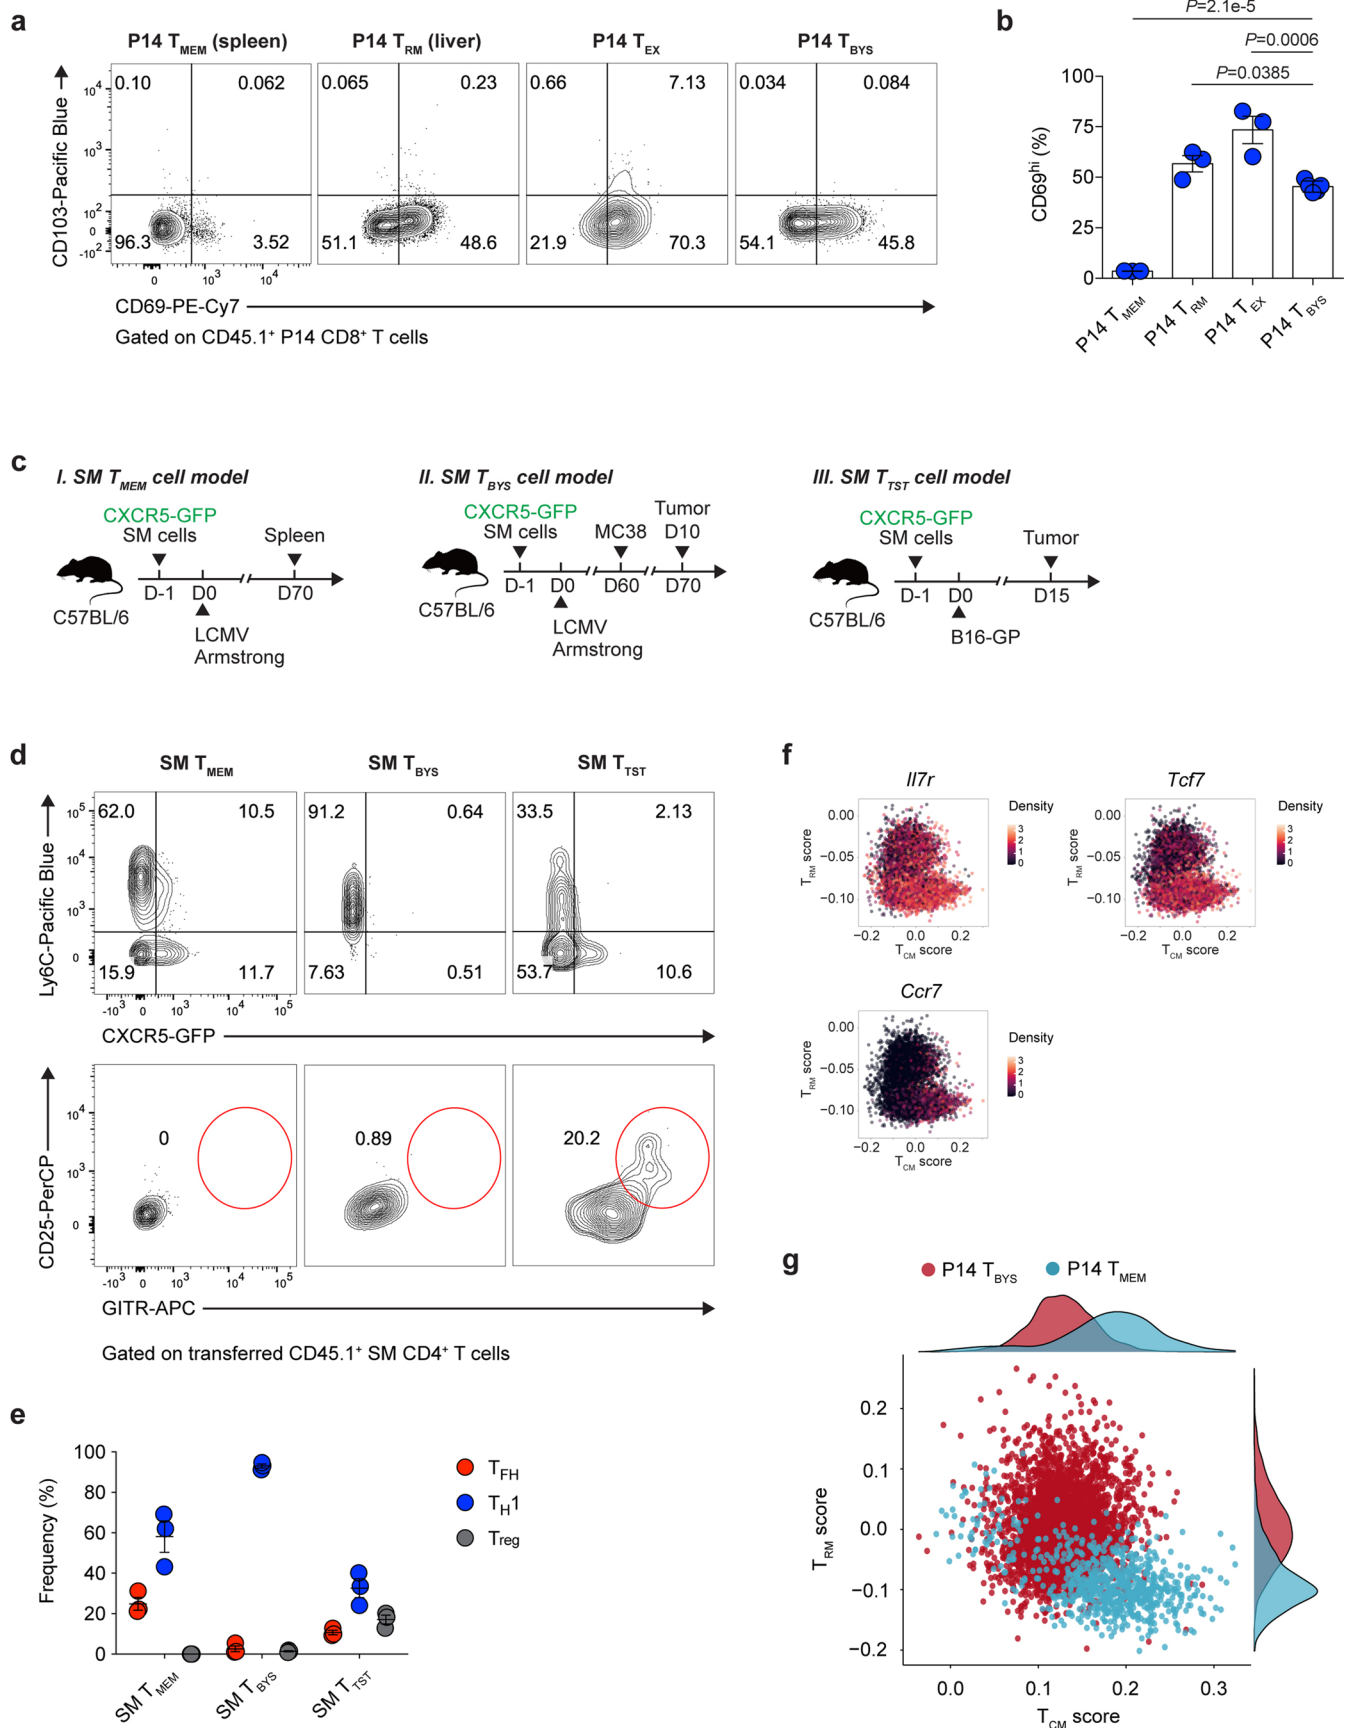

Extended Data Fig. 2 | See next page for caption.

Extended Data Fig. 2 | Differentiation patterns of tumor-infiltrating virus-specific T$_{BYS}$ cells. a, Flow cytometry analysis of CD69 and CD103 expressions in splenic P14 T$_{MEM}$ cells, P14 T$_{RM}$ cells (liver), tumor-specific P14 T$_{EX}$ cells and tumor-infiltrating P14 T$_{BYS}$ cells. **b**, Frequencies of CD69^{hi} cells in P14 T$_{MEM}$ cells (n = 3 mice), P14 T$_{RM}$ cells (n = 3 mice), P14 T$_{EX}$ cells (n = 3 mice) and P14 T$_{BYS}$ cells (n = 5 mice) in a. **c**, Schematic graph of the experimental design. (I) SM T$_{MEM}$ cell model: CD45.1^{+} CXCR5-GFP SM CD4^{+} T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2^{+}), which were then infected with LCMV Armstrong. On day 70 after infection, splenic SM T$_{MEM}$ cells were analyzed. (II) SM T$_{BYS}$ cell model: congenic CD45.1^{+} CXCR5-GFP SM CD4^{+} T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2^{+}), which were then infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On day 10^{-}post tumor engraftment, tumor-infiltrating SM T$_{BYS}$ cells were analyzed.

(III) SM T$_{TST}$ cell model: congenic CXCR5-GFP SM CD4^{+} T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2^{+}), which were then engrafted with B16-GP cells. On day 15-post tumor engraftment, SM T$_{TST}$ cells were analyzed. **d**, Flow cytometry analysis of CXCR5/Ly6C expressions (top panel) and GITR/CD25 expressions (bottom panel) in SM T$_{MEM}$, SM T$_{BYS}$ and SM T$_{TST}$ cells. **e**, Frequencies of CXCR5^{+}Ly6C^{-} T$_{FH}$, CXCR5^{-}Ly6C^{+} T$_{H}$1 and GITR^{+}CD25^{+} T$_{reg}$ cells in SM T$_{MEM}$ (n = 3 mice), SM T$_{BYS}$ (n = 3 mice) and SM T$_{TST}$ (n = 3 mice) cells. **f**, Expression profiles of *Il7r*, *Tcf7* and *Ccr7* of 3,565 SM T$_{BYS}$ cells and 5,648 SM T$_{MEM}$ cells in T$_{CM}$ versus T$_{RM}$ score space. **g**, Geneset scoring analysis of 3,322 P14 T$_{BYS}$ cells and 764 P14 T$_{MEM}$ cells. Density of cells in T$_{CM}$ versus T$_{RM}$ score space annotated by cell type are depicted. All the data are representative of two independent experiments. One-way ANOVA with Turkey's test was used in b. Error bars (b, e) indicate s.e.m.

Extended Data Fig. 3 | Characteristics of tumor-infiltrating endogenous virus-specific T_{BYS} cells. a, Schematic graph of the experimental design. (I) Endogenous T_{MEM} cells: naïve C57BL/6 mice were infected with LCMV Armstrong and splenic LCMV-specific T cells were determined by peptide stimulation assay on day 70 after infection. (II) Endogenous T_{BYS} cells: naïve C57BL/6 mice were infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On day 10 after tumor engraftment, tumor-infiltrating LCMV-specific T cells were determined by peptide stimulation assay. (III) MC38 TIL of uninfected mice: naïve C57BL/6 mice were engrafted with MC38 cells and tumor-infiltrating T cells were determined by peptide stimulation assay on day 10 after tumor engraftment. **b**, Flow cytometry analysis of IFN-γ and TNF-α expressions in CD8$^+$ T cells originating from spleens of LCMV Armstrong-infected mice, MC38 tumors of LCMV Armstrong-infected mice or MC38 tumors of uninfected mice under the condition of LCMV GP$_{33-41}$ or GP$_{276-286}$ or NP$_{396-404}$ peptide stimulation. **c**, Flow cytometry analysis of IFN-γ and TNF-α expressions in CD4$^+$ T cells originating from spleens of LCMV Armstrong-infected mice, MC38 tumors of LCMV Armstrong-infected mice or MC38 tumors of uninfected mice under the condition of LCMV GP$_{66-77}$ peptide stimulation. **d**, Frequencies of IFN-γ$^+$ cells in CD8$^+$ T cells (LCMV GP$_{33-41}$ or GP$_{276-286}$ or NP$_{396-404}$ stimulation) or CD4$^+$ T cells (LCMV GP$_{66-77}$ stimulation) originating from spleens of LCMV Armstrong-infected mice (memory) or MC38 tumors of LCMV Armstrong-infected mice (bystander). Memory (n = 3 (GP$_{33-41}$), 3 (GP$_{276-286}$), 3 (NP$_{396-404}$), or 3 (GP$_{66-77}$) mice), bystander (n = 4 (GP$_{33-41}$), 3 (GP$_{276-286}$), 4 (NP$_{396-404}$), or 5 (GP$_{66-77}$) mice). **e**, Numbers of IFN-γ-expressing CD8$^+$ T cells (LCMV GP$_{33-41}$ or GP$_{276-286}$ or NP$_{396-404}$ stimulation) or IFN-γ-expressing CD4$^+$ T cells (LCMV GP$_{66-77}$ stimulation) originating from MC38 tumors of LCMV Armstrong-infected mice. n = 4 (GP$_{33-41}$), 4 (GP$_{276-286}$), 4 (NP$_{396-404}$), or 4 (GP$_{66-77}$) mice. **f**, Schematic graph of the experimental design. Naïve C57BL/6 mice were infected with LCMV Armstrong and engrafted with B16F10 cells on day 60 after infection. On day 10 after tumor engraftment, tumor-infiltrating LCMV-specific T cells were determined by peptide stimulation assay. **g**, **h**, Frequencies (g) and numbers (h) of IFN-γ-expressing CD8$^+$ T cells (LCMV GP$_{33-41}$ or GP$_{276-286}$ or NP$_{396-404}$ stimulation) or IFN-γ-expressing CD4$^+$ T cells (LCMV GP$_{66-77}$ stimulation) originating from B16F10 tumors of LCMV Armstrong-infected mice. n = 5 (GP$_{33-41}$), 5 (GP$_{276-286}$), 5 (NP$_{396-404}$), or 5 (GP$_{66-77}$) mice in g and h. All the data are representative of two independent experiments. Two-tailed unpaired Student's t-test was used in d. Error bars (d, e, g, h) indicate s.e.m.
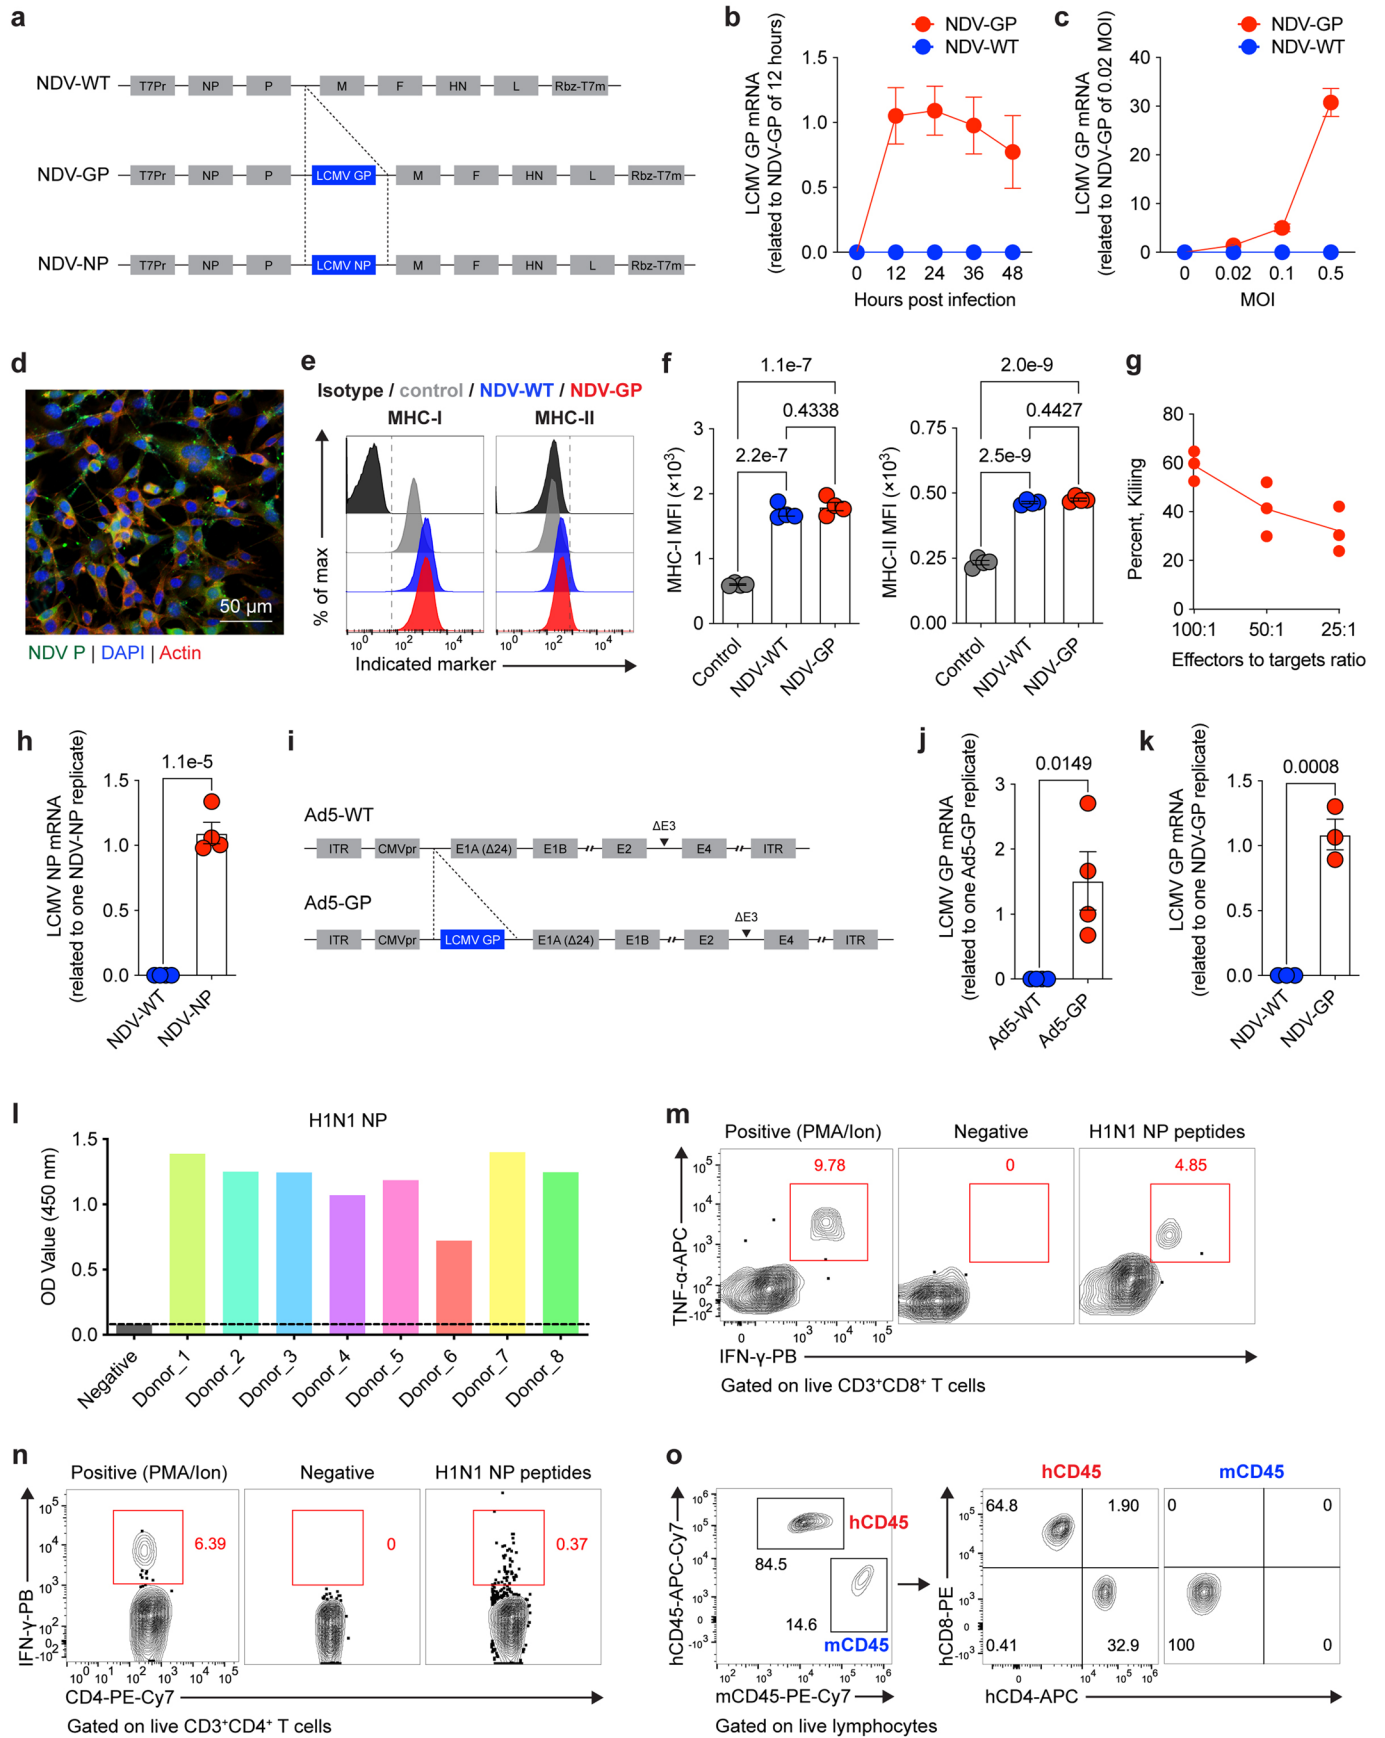

Extended Data Fig. 4 | See next page for caption.

Extended Data Fig. 4 | Construction of oncolytic viruses expressing LCMV viral proteins and humanized mice. a, Schematic graph of NDV rSG10 (NDV-WT) or modified NDV rSG10 expressing LCMV GP (NDV-GP) or LCMV NP (NDV-NP). **b**, Relative quantification of LCMV GP mRNA in MC38 cells at indicated timepoints (12, 24, 36 and 48 hours) after initial exposure to the 0.1 multiplicity of infection (MOI) of NDV-WT (n = 3 wells of cultured cells with biological independence) or NDV-GP (n = 3 wells of cultured cells with biological independence). **c**, Relative quantification of LCMV GP mRNA in MC38 cells at 24 hours after initial exposure to the indicated MOIs (0, 0.02, 0.1 and 0.5) of NDV-WT (n = 3 wells of cultured cells with biological independence) or NDV-GP (n = 3 wells of cultured cells with biological independence). **d**, Immunofluorescence microscopy of MC38 cells pre-treated with NDV-GP at MOI of 0.5 for 24 hours. Scale bar, 50 μm. Red indicates actin, blue indicates DAPI and green indicates NDV P protein. **e**, Flow cytometry analysis of MHC-I (left) and MHC-II (right) expressions in MC38 cells infected for 24 hours with NDV-WT or NDV-GP at MOI of 0.5 or in uninfected MC38 cells. **f**, MHC-I (left) and MHC-II (right) expression levels among MC38 cells in e. Control (n = 4 wells of cultured cells with biological independence), NDV-WT (n = 4 wells of cultured cells with biological independence) and NDV-GP (n = 4 wells of cultured cells with biological independence). **g**, *Ex vitro* killing efficiency of LCMV-specific CD8⁺ T cells to NDV-GP-infected MC38 cells. The n value was 3 (wells of cultured cells with biological independence) in each group. **h**, Relative quantification of LCMV NP mRNA in MC38 cells after 24-hour exposure to 0.5 MOI of NDV-WT (n = 4 wells of cultured cells with biological independence) or NDV-NP (n = 4 wells of cultured cells with

biological independence). **i**, Schematic graph of Ad5 (Ad5-WT) or modified Ad5 expressing LCMV GP (Ad5-GP). **j**, Relative quantification of LCMV GP mRNA in MC38 cells after 24-hour exposure to 0.5 MOI of Ad5-WT (n = 4 wells of cultured cells with biological independence) or Ad5-GP (n = 4 wells of cultured cells with biological independence). **k**, Relative quantification of LCMV GP mRNA in B16F10 cells after 24-hour exposure to 0.5 MOI of NDV-WT (n = 3 wells of cultured cells with biological independence) or NDV-GP (n = 3 wells of cultured cells with biological independence). **l**, ELISA binding assays of healthy donor sera to ELISA plate coating of H1N1 NP protein. **m**, Flow cytometry analysis of CD3⁺CD8⁺ T cells from the PBMCs of donor_1 under the condition of PMA/Ion stimulation (positive control) or DMSO (negative control) or H1N1 NP peptides. The numbers adjacent to the outlined areas indicate the frequencies of IFN-γ⁺TNF-α⁺ cells in CD3⁺CD8⁺ T cells. **n**, Flow cytometry analysis of CD3⁺CD4⁺ T cells from the PBMCs of donor_1 under the condition of PMA/Ion stimulation (positive control) or DMSO (negative control) or H1N1 NP peptides. The numbers adjacent to the outlined areas indicate the frequencies of IFN-γ⁺ cells in CD3⁺CD4⁺ T cells. **o**, Flow cytometry analysis of PBMCs of humanized NCG mice. Left panel, the numbers adjacent to the outlined areas indicate the proportions of human CD45⁺ (hCD45) cells or mouse CD45⁺ (mCD45) cells in live lymphocytes; right panel, the numbers adjacent to the outlined areas indicate the proportions of human CD8⁺ (hCD8) or human CD4⁺ (hCD4) T cells in hCD45 or mCD45 cells, respectively. Data in b-h, j-o are representative of at least two independent experiments. One-way ANOVA with Turkey's test was used in f. Two-tailed unpaired Student's *t*-test was used in h, j, k. Error bars (b, c, f, h, j, k) indicate s.e.m.
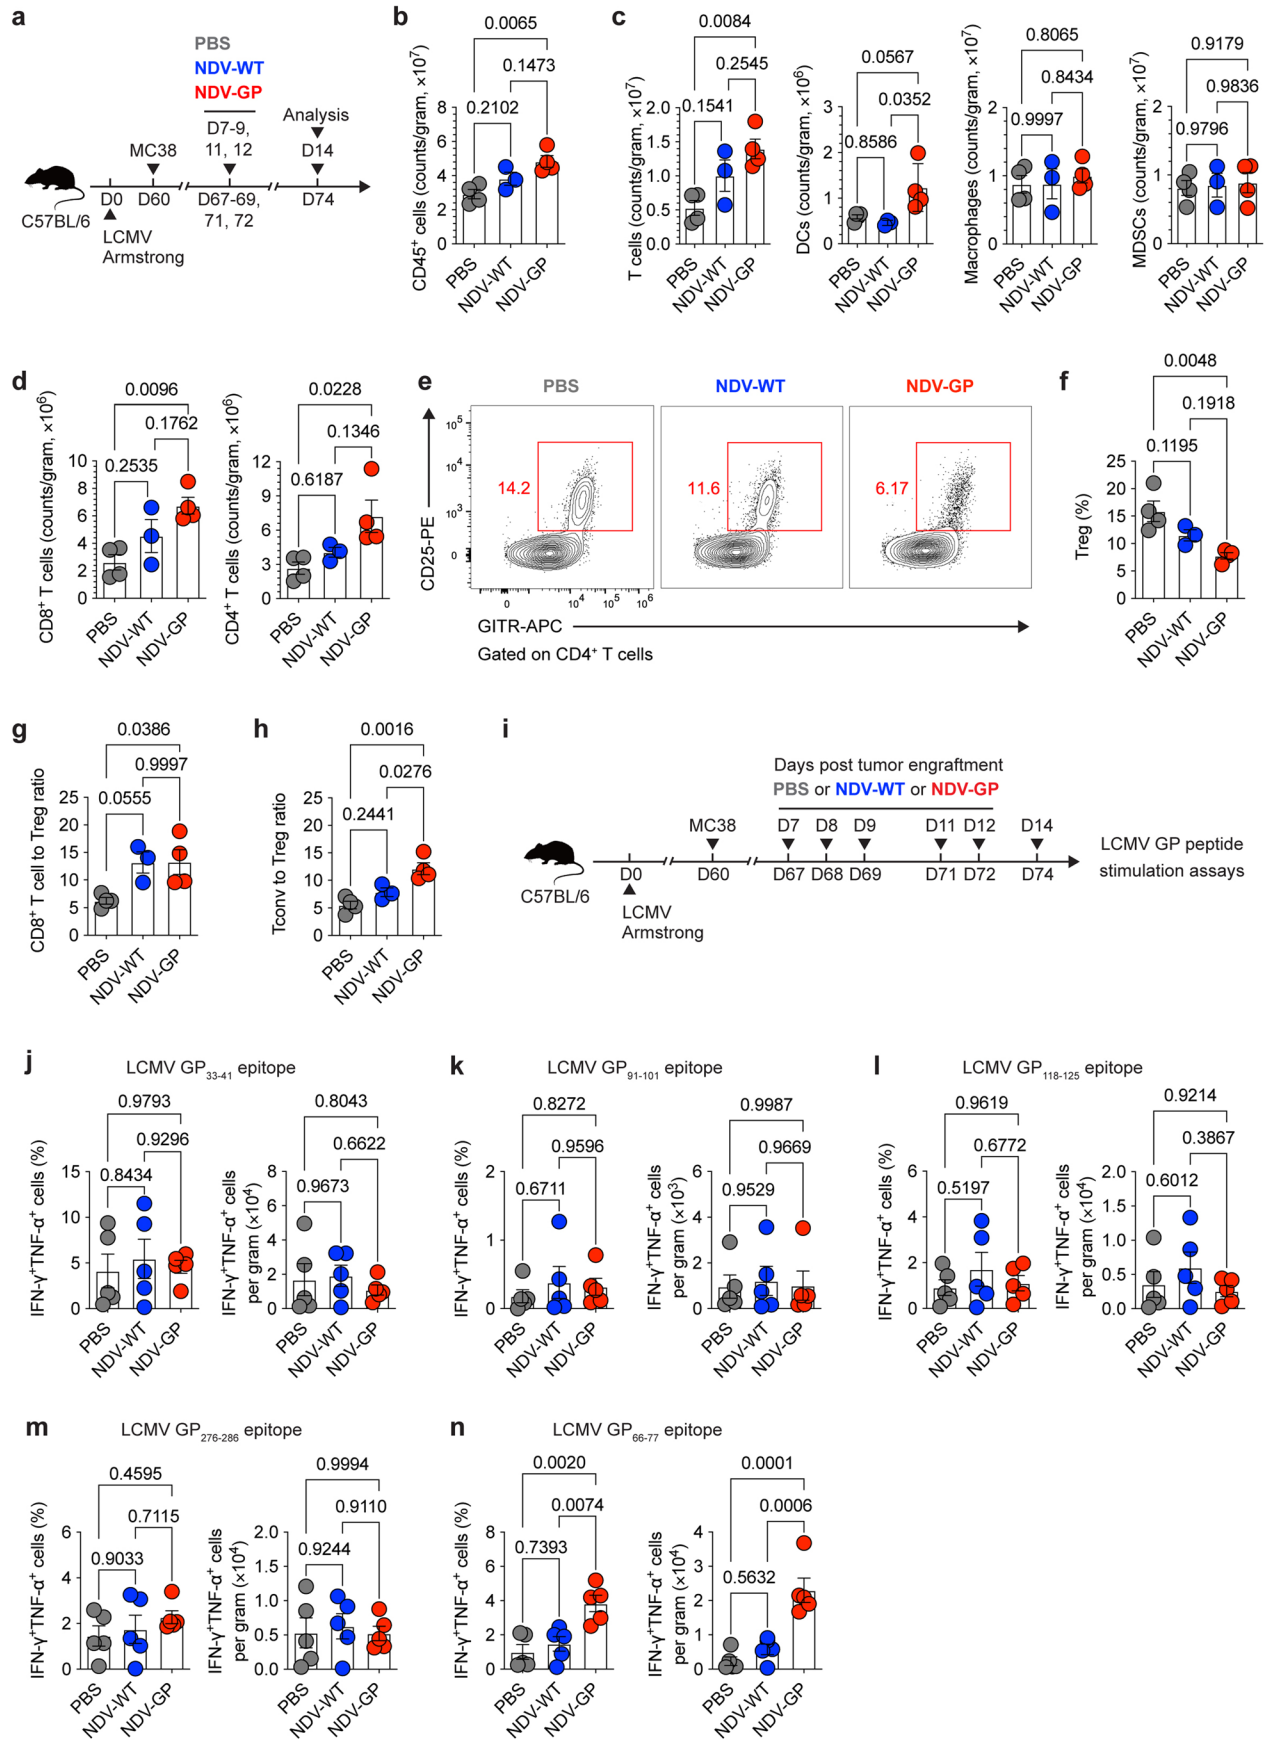

Extended Data Fig. 5 | See next page for caption.

**Extended Data Fig. 5 | Tumor-infiltrating immune cell responses upon intratumoral administration of NDV-GP. a**, Schematic graph of the experimental design for b-h. Naïve C57BL/6 mice were infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On day 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally treated with PBS or NDV-WT or NDV-GP. On day 14 after tumor engraftment, tumor-infiltrating immune cells were analyzed. **b**, Numbers of MC38 tumor-infiltrating CD45$^+$ cells in mice intratumorally administrated with PBS (n = 4 mice) or NDV-WT (n = 3 mice) or NDV-GP (n = 4 mice) as described in a. **c**, Numbers of MC38 tumor-infiltrating CD45$^+$CD3$^+$ T cells, CD45$^+$F4/80$^-$CD11c$^+$MHC-II$^+$ dendritic cells (DCs), CD45$^+$F4/80$^+$CD11b$^+$MHC-II$^+$ macrophages, and CD45$^+$F4/80$^+$CD11b$^+$Ly-6C$^{intermediate\,to\,high}$ myeloid-derived suppressor cells (MDSCs) in mice intratumorally administrated with PBS (n = 4 mice) or NDV-WT (n = 3 mice) or NDV-GP (n = 4 mice). **d**, Numbers of tumor-infiltrating CD8$^+$ T cells (left) and CD4$^+$ T cells (right) in mice intratumorally administrated with PBS (n = 4 mice) or NDV-WT (n = 3 mice) or NDV-GP (n = 4 mice). **e**, Flow cytometry analysis of GITR and CD25 expressions in tumor-infiltrating CD4$^+$ T cells in mice intratumorally administrated with PBS or NDV-WT or NDV-GP. The numbers adjacent to the outlined areas indicate the percentages of GITR$^+$CD25$^+$ T$_{reg}$ cells in CD4$^+$ T cells.

f, Frequencies of tumor-infiltrating GITR$^+$CD25$^+$ T$_{reg}$ cells in CD4$^+$ T cells. PBS (n = 4 mice), NDV-WT (n = 3 mice), and NDV-GP (n = 4 mice). **g**, Ratios of tumor-infiltrating CD8$^+$ T cells to T$_{reg}$ cells. PBS (n = 4 mice), NDV-WT (n = 3 mice), and NDV-GP (n = 4 mice). **h**, Ratios of tumor-infiltrating T$_{conv}$ cells to T$_{reg}$ cells. PBS (n = 4 mice), NDV-WT (n = 3 mice), and NDV-GP (n = 4 mice). **i**, Schematic graph of the experimental design for j-n. Naïve C57BL/6 mice were infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On day 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally administrated with PBS or NDV-WT or NDV-GP. On day 14 after tumor engraftment, LCMV-specific T cells were determined by peptide stimulation assays in MC38 tumors of mice in each group. **j-m**, Frequencies and numbers of IFN-γ$^+$TNF-α$^+$ cells in tumor-infiltrating CD8$^+$ T cells under the condition of LCMV GP$_{33-41}$ (j), GP$_{91-101}$ (k), GP$_{118-125}$ (l) and GP$_{276-286}$ (m) stimulation. **n**, Frequency and number of IFN-γ$^+$TNF-α$^+$ cells in tumor-infiltrating CD4$^+$ T cells under the condition of LCMV GP$_{66-77}$ stimulation. PBS (n = 5 mice), NDV-WT (n = 5 mice) and NDV-GP (n = 5 mice) in j-n. All the data are representative of at least two independent experiments. One-way ANOVA with Turkey's test was used in b-d, f-h, j-n. Error bars (b-d, f-h, j-n) indicate s.e.m.
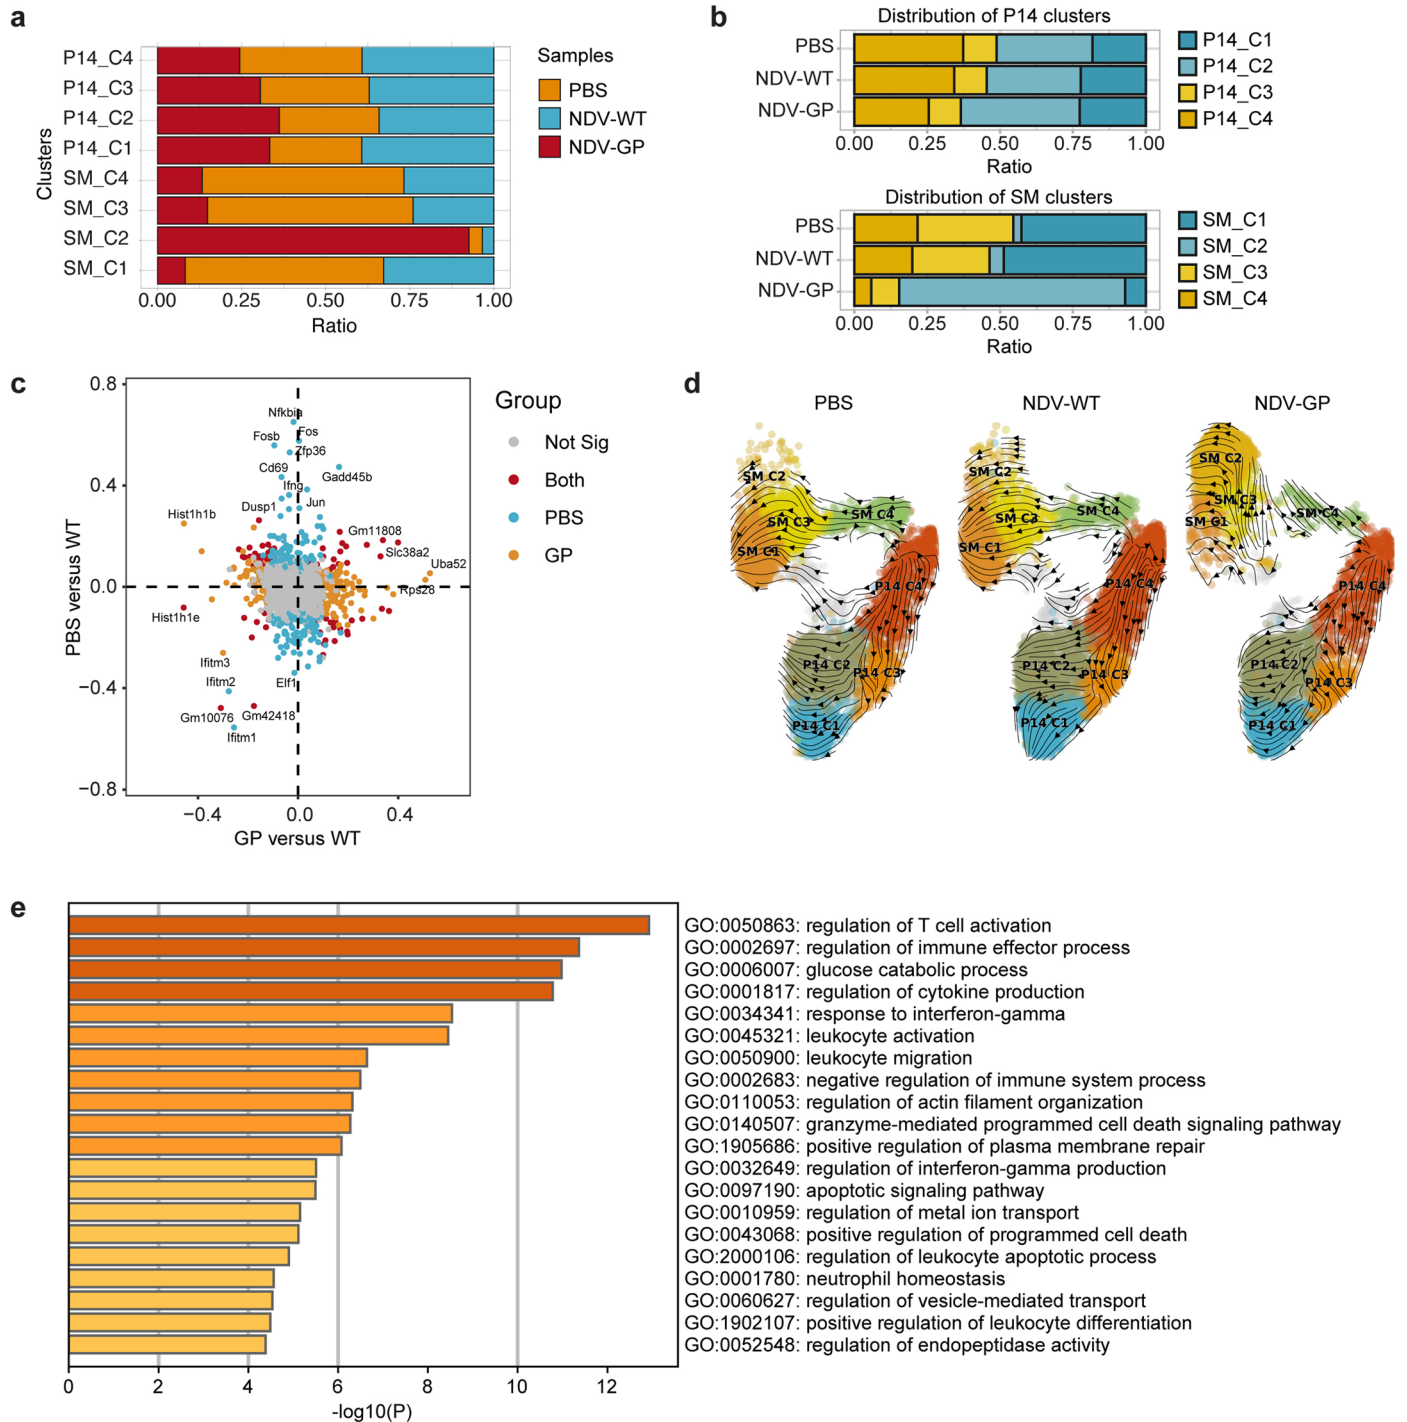

Extended Data Fig. 6 | Analyses of NDV-GP-mediated T_{BYS} cell responses by scRNA-seq. a, Barplot showing the proportion of cells originating from PBS (6,571 cells), NDV-WT (5,397 cells) and NDV-GP (5,951 cells) groups in each cluster of P14 T_{BYS} cells (C1 to C4) or SM T_{BYS} cells (C1 to C4). **b**, Barplot showing the frequency distribution of each cluster in P14 or SM T_{BYS} cells from PBS (6,571 cells), NDV-WT (5,397 cells) or NDV-GP (5,951 cells) samples. **c**, Plot showing differential expressed genes between NDV-GP_P14 T_{BYS} cells and NDV-WT_P14

T_{BYS} cells (X-axis) and differential expressed genes between PBS_P14 T_{BYS} cells and NDV-WT_P14 T_{BYS} cells (Y-axis). **d**, Visualization of RNA velocities on diffusion map of P14 T_{BYS} cells and SM T_{BYS} cells. PBS (left, 6,571 cells), NDV-WT (middle, 5,397 cells) and NDV-GP (right, 5,951 cells). **e**, Gene Ontology analyses of up-regulated genes in SM cluster 2 as compared to SM cluster 1/3. *P* values in e were calculated based on the cumulative hypergeometric distribution.

Extended Data Fig. 7 | SM T$_{BYS}$ cell differentiation upon intratumoral administration of NDV-GP. a, Schematic graph of the experimental design. Congenic CD45.1$^+$ CXCR5-GFP SM CD4$^+$ T cells were adoptively transferred into naïve C57BL/6 recipients (CD45.2$^+$), which were then infected with LCMV Armstrong and engrafted with MC38 cells on day 60 after infection. On day 7, 8, 9, 11 and 12-post tumor engraftment, recipients were intratumorally treated with PBS or NDV-WT or NDV-GP. On day 14-post tumor engraftment, tumor-infiltrating CXCR5-GFP SM CD4$^+$ T cells were analyzed. **b**, Flow cytometry analysis of CXCR5 and Ly6C expressions in SM T$_{BYS}$ cells. **c**, Frequencies of CXCR5$^+$ cells in SM T$_{BYS}$ cells. PBS (n = 4 mice), NDV-WT (n = 4 mice) and NDV-GP (n = 4 mice) in c. **d**, Flow cytometry analysis of TCF-1 and T-bet expressions in Ly108^{lo}CD39^{hi}

and Ly108^{hi}CD39^{lo} SM T$_{BYS}$ cells from NDV-GP-treated MC38 tumors engrafted on LCMV Armstrong-infected mice. **e**, Expression levels of TCF-1 and T-bet in Ly108^{lo}CD39^{hi} (n = 6 mice) and Ly108^{hi}CD39^{lo} (n = 6 mice) SM T$_{BYS}$ cells described in d. **f, g**, Flow cytometry analysis of GzmB-expressing CD8$^+$ T cells (f) and GzmB-expressing CD4$^+$ T cells (g) from the spleens of LCMV Armstrong-infected WT (n = 6 mice) and $Gzmb^{KO}$ (n = 3 mice) mice on day 60$^-$post infection. The numbers adjacent to the outlined areas in the left flow data panel indicate the percentages of GzmB-expressing cells in CD8$^+$ T cells (f) or CD4$^+$ T cells (g), which are summarized on the right panel. All data are representative of at least two independent experiments. One-way ANOVA with Turkey's test was used in c. Two-tailed unpaired Student's t-test was used in e-g. Error bars (c, e-g) indicate s.e.m.
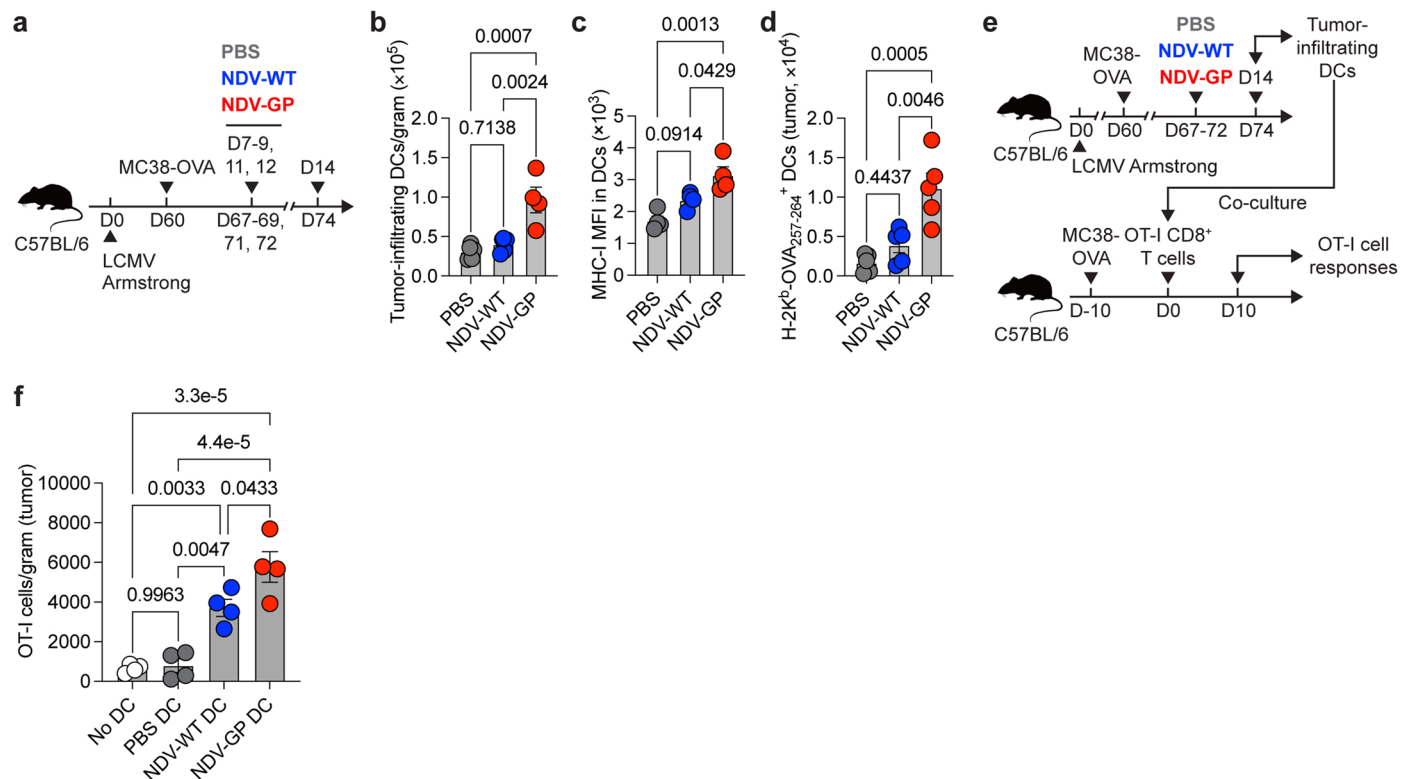

Extended Data Fig. 8 | DCs contribute to the OV-BYTE therapy-induced T cell epitope spreading. a, Schematic graph of the experimental design. Naïve C57BL/6 mice were infected with LCMV Armstrong and engrafted with MC38-OVA cells on day 60 after infection. These tumor-engrafted mice were then daily treated with PBS or NDV-WT or NDV-GP on day 7, 8, 9, 11 and 12 after tumor inoculation. On day 14, tumor-infiltrating immune cells were analyzed. **b**, Number of CD45$^+$F4/80$^-$CD11c$^+$MHC-II$^+$ DCs originating from PBS- (n = 5 mice) or NDV-WT- (n = 5 mice) or NDV-GP-treated (n = 4 mice) MC38-OVA tumors described in a. **c**, MHC-I expression levels in CD45$^+$F4/80$^-$CD11c$^+$MHC-II$^+$ DCs originating from PBS- (n = 4 mice) or NDV-WT- (n = 4 mice) or NDV-GP-treated (n = 4 mice) MC38-OVA tumors described in a. **d**, Number of CD45$^+$F4/80$^-$CD11c$^+$I-A^b+H-2K^b-OVA$_{257-264}^+$ DCs originating from PBS- (n = 5 mice) or NDV-WT- (n = 5 mice) or NDV-GP-treated (n = 5 mice) MC38-OVA tumors described in a.

e, Schematic graph of the experimental design. Naïve C57BL/6 mice were infected with LCMV Armstrong and engrafted with MC38-OVA cells on day 60 after infection. These mice were then treated with PBS or NDV-WT or NDV-GP from day 7 to day 12 after tumor inoculation. On day 14, tumor-infiltrating DCs from PBS or NDV-WT or NDV-GP groups were isolated, labeled with OVA$_{257-264}$ peptide and cultured with naïve OT-I CD8$^+$ T cells overnight. The next day, OT-I CD8$^+$ T cells were transferred into a new cohort of MC38-OVA-engrafted mice and analyzed on day 10-post transfer. **f**, Numbers of MC38-OVA tumor-infiltrating OT-I CD8$^+$ T cells pre-cultured with DCs from PBS (n = 4 mice) or NDV-WT (n = 4 mice) or NDV-GP (n = 4 mice) groups and OT-I CD8$^+$ T cells without DC co-culture (n = 4 mice) as described in e. All the data are representative of two independent experiments. One-way ANOVA with Turkey's test was used in b-d, f. Error bars (b-d, f) indicate s.e.m.
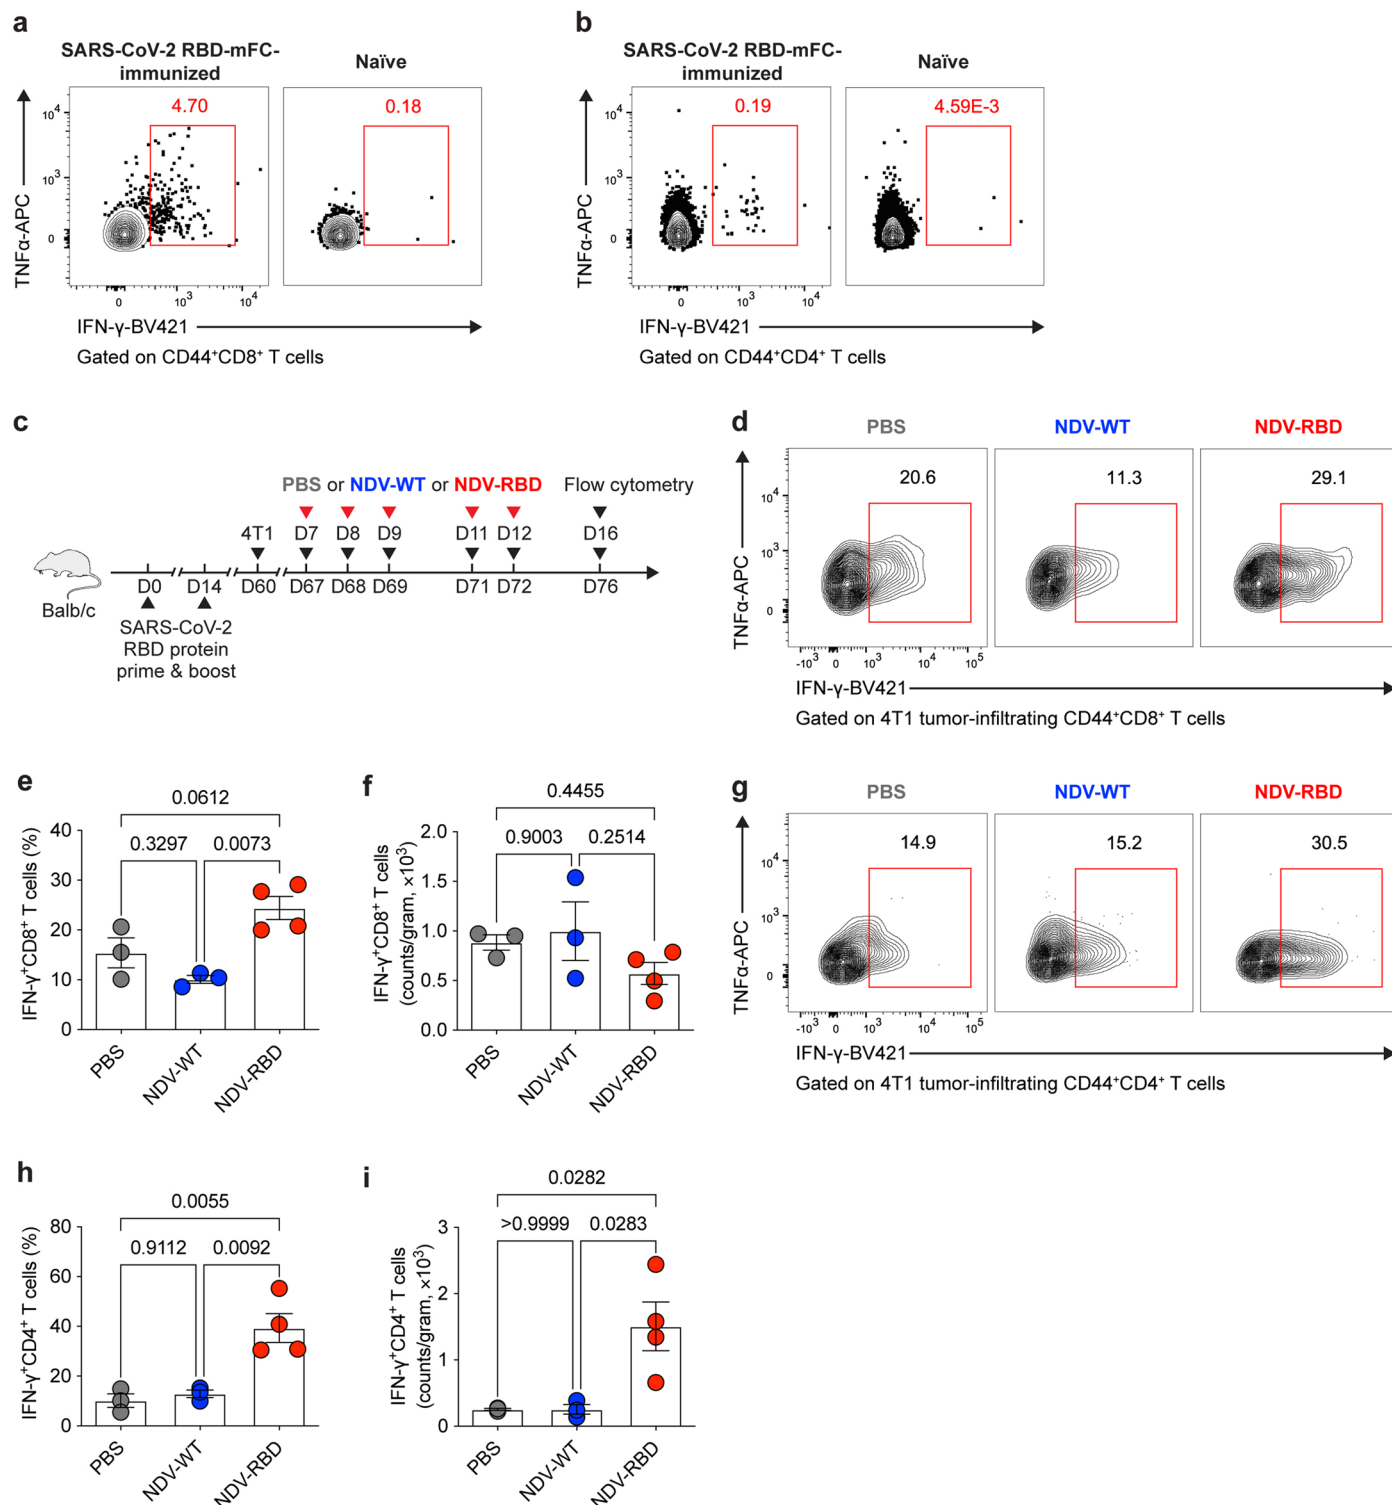

Extended Data Fig. 9 | SARS-CoV-2 RBD-specific T$_{BYS}$ cell responses to NDV-RBD. a, b, Flow cytometry analysis of splenic CD8$^+$ T cells (a) and CD4$^+$ T cells (b) under the condition of SARS-CoV-2 protein stimulation. The numbers adjacent to the outlined areas indicate the frequencies of IFN-γ$^+$ cells in CD44$^+$CD8$^+$ T cells (a) or CD44$^+$CD4$^+$ T cells (b). **c,** Schematic graph of the experimental design. Naïve Balb/c mice were immunized with SARS-CoV-2 RBD protein and engrafted with 4T1 cells on day 60 after immunization. On day 7, 8, 9, 11 and 12 after tumor engraftment, recipients were intratumorally administrated with PBS or NDV-WT or NDV-RBD. On day 16 after tumor engraftment, tumor-infiltrating T cells were analyzed. **d,** Flow cytometry analysis of 4T1 tumor-infiltrating CD44$^+$CD8$^+$ T cells under the condition of SARS-CoV-2 S1 peptide pool stimulation. The

numbers adjacent to the outlined areas indicate the frequencies of IFN-γ$^+$ cells in CD44$^+$CD8$^+$ T cells. **e, f,** Frequency (e) and number (f) of SARS-CoV-2 S1-stimulated IFN-γ$^+$CD8$^+$ T cells in d. **g,** Flow cytometry analysis of 4T1 tumor-infiltrating CD44$^+$CD4$^+$ T cells under the condition of SARS-CoV-2 S1 peptide pool stimulation. The numbers adjacent to the outlined areas indicate the frequencies of IFN-γ$^+$ cells in CD44$^+$CD4$^+$ T cells. **h, i,** Frequency (h) and number (i) of SARS-CoV-2 S1-stimulated IFN-γ$^+$CD4$^+$ T cells in g. PBS (n = 3 mice), NDV-WT (n = 3 mice) and NDV-RBD (n = 4 mice) in e, f, h, i. All the data are representative of two independent experiments. One-way ANOVA with Turkey's test was used in e, f, h, i. Error bars (e, f, h, i) indicate s.e.m.
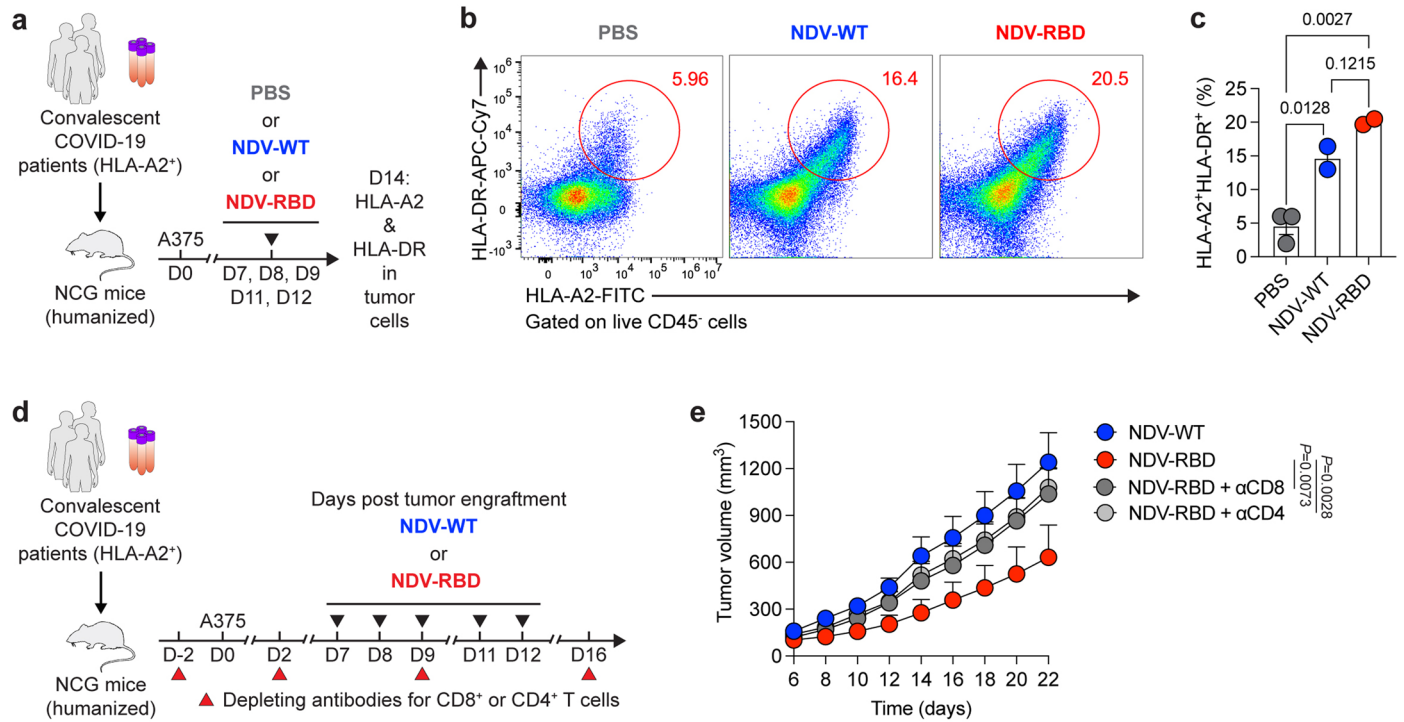

Extended Data Fig. 10 | Both CD8+ and CD4+ T cells are indispensable for the anti-tumor function of OV-BYTE therapy in humanized NCG mice.
a, Schematic experimental design. NCG mice were engrafted with PBMCs from the HLA-A2-positive convalescent COVID-19 patients. Reconstructed humanized NCG mice were then engrafted with A375 cells and then intratumorally administered with PBS or NDV-WT or NDV-RBD on day 7, 8, 9, 11 and 12 after tumor engraftment. On day 14-post tumor engraftment, HLA-A2 and HLA-DR expression levels were detected in A375 tumor cells. **b**, Flow cytometry analysis of HLA-A2+HLA-DR+ cells in CD45− cells from PBS- or NDV-WT- or NDV-RBD-treated A375 tumors as described in a. The numbers adjacent to the outlined areas indicate the frequencies of HLA-A2+HLA-DR+ cells in CD45− cells. **c**, Frequencies of HLA-A2+HLA-DR+ cells in CD45− cells from PBS- (n = 3 mice) or NDV-WT- (n = 2 mice) or NDV-RBD-treated (n = 2 mice) A375 tumors. **d**, Schematic experimental

design. NCG mice were engrafted with PBMCs from the HLA-A2-positive convalescent COVID-19 patients. Then, reconstructed humanized NCG mice were engrafted with A375 cells and then intratumorally administered with NDV-WT or NDV-RBD on day 7, 8, 9, 11 and 12 after tumor engraftment. Meanwhile, recipients were intraperitoneally injected with depleting antibodies for CD8+ or CD4+ T cells on indicated time points. **e**, Tumor growth curve of A375 tumor-bearing NCG mice intratumorally treated with NDV-WT or NDV-RBD in the presence or absence of depleting antibody for CD8+ or CD4+ T cells. NDV-WT (n = 5 mice), NDV-RBD (n = 6 mice), NDV-RBD/αCD8 (n = 6 mice) and NDV-RBD/αCD4 (n = 5 mice). All the data are representative of two independent experiments. One-way ANOVA with Turkey's test was used in c. Two-way ANOVA was used to compare tumor growth curves in e. Error bars (c, e) indicate s.e.m.

Reporting Summary

Nature Portfolio wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Portfolio policies, see our Editorial Policies and the Editorial Policy Checklist.

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

n/a	Confirmed	
☐	☒	The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement
☐	☒	A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly
☐	☒	The statistical test(s) used AND whether they are one- or two-sided *Only common tests should be described solely by name; describe more complex techniques in the Methods section.*
☒	☐	A description of all covariates tested
☐	☒	A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons
☐	☒	A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)
☐	☒	For null hypothesis testing, the test statistic (e.g. F, t, r) with confidence intervals, effect sizes, degrees of freedom and P value noted *Give P values as exact values whenever suitable.*
☒	☐	For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings
☒	☐	For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes
☒	☐	Estimates of effect sizes (e.g. Cohen's d, Pearson's r), indicating how they were calculated

Our web collection on statistics for biologists contains articles on many of the points above.

Software and code

Policy information about availability of computer code

Data collection	Flow cytometry data were collected by FACSDiva (version 7.0) software in FACSCanto II (BD Biosciences) or FACSFortesa (BD Biosciences). Single-cell sequencing data were collected using Cell Ranger software (10x Genomics) version 6.1.1. Immunofluorescence images were acquired with a Zeiss LSM 510 confocal fluorescence microscope.
Data analysis	Flow cytometry data were analyzed with FlowJo (version 10.4.0). Statistical analysis was performed with Prism 9.0 (GraphPad). For bioinformatic analyses, we primarily used existing computational tools, and we cited all the sources of the tools we used: https://github.com/satijalab/seurat (v. 4.1.1); https://github.com/plger/scDblFinder (v. 1.8.0); https://github.com/theislab/scvelo (v. 0.2.4); https://github.com/velocyto-team/velocyto.py (v. 0.17.17); https://github.com/dylkot/cNMF (v. 1.4); https://github.com/ncborcherding/scRepertoire (v. 1.8.0); https://github.com/yannabraham/Radviz (v. 0.9.3). Immunofluorescence images were processed with LSM Image Examiner (version 4.0).

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Portfolio guidelines for submitting code & software for further information.

Data

All manuscripts must include a <u>data availability statement</u>. This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A description of any restrictions on data availability
- For clinical datasets or third party data, please ensure that the statement adheres to our <u>policy</u>

The scRNA-seq data of MC38 tumor-infiltrating P14/SM TBYS cells and conventional memory SM cells, the scTCR-seq data of MC38 tumor-infiltrating CD8+ T cells and the bulk TCR-seq data of MC38 tumor-infiltrating p15E-specific CD8+ T cells in this study have been deposited with GEO under accession code GSE222002 (https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE222002). Public scRNA-seq and bulk RNA-seq data reanalyzed here are available under accession codes (GSE182276, GSE131847 and GSE128197). Source data for Figures 1-8 and Extended Data Figures 1-10 have been provided as Source Data files.

Research involving human participants, their data, or biological material

Reporting on sex and gender	We enrolled a cohort containing 8 HLA-A2-positive healthy volunteers (4 female and 4 male) and a cohort containing 4 HLA-A2-positive convalescent COVID-19 patients (2 female and 2 male). Inclusion criteria was not sex-based but rather based on their established T cell memory to H1N1 and SARS-CoV-2 infections.
Reporting on race, ethnicity, or other socially relevant groupings	All the participants in this study were Chinese of HLA-A2 restriction and harbor T cell memory specific to H1N1 NP or SARS-CoV-2 RBD.
Population characteristics	Cohort 1: healthy volunteers, 4 female and 4 male, age range: 27-35, HLA-A2+, infection history of H1N1 as diagnosed by functional ELISA assays and H1N1 NP peptide stimulation assay; Cohort 2: convalescent COVID-19 patients, 2 female and 2 male, age range: 36-50, HLA-A2+, infection history of SARS-CoV-2 during Feb., 2020 to Apr., 2020.
Recruitment	Healthy volunteers with a history of H1N1 infection (as diagnosed by ELISA assays) and H1N1 NP-specific T cell memory were recruited in the study (as suggested by H1N1 NP peptide stimulation assay). Convalescent COVID-19 patients (as diagnosed by ELISA assays) with SARS-CoV-2 RBD-specific T cell memory (as suggested by SARS-CoV-2 RBD protein stimulation assay) were recruited in the study. Healthy donors or convalescent COVID-19 patients were recruited under Institutional Review Board approvals at Chongqing Public Health Medical Center (2020-023-01-KY).
Ethics oversight	The study received Institutional Review Board approvals at Chongqing Public Health Medical Center (2020-023-01-KY). All volunteers were provided written informed consent.

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

☒ Life sciences   ☐ Behavioural & social sciences   ☐ Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see <u>nature.com/documents/nr-reporting-summary-flat.pdf</u>

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

Sample size	No statistical methods were used to predetermine the sample size. In most cases, each experimental group contains 4-6 biological replicates (flow cytometry, RT-PCR) or 8-12 biological replicates (tumor survival assay, scRNA-seq, scTCR-seq, bulk TCR-seq). The sample sizes in the study were empirically determined to optimized numbers necessary for statistical significance according to previous published studies of our own and other research groups (He, R. et al., Nature, 2016, PMID: 27501245; Khan, O. et al., Nature, 2019, PMID: 31207603; Huang, Q. et al., Cell, 2022, PMID: 36208623).
Data exclusions	No data were excluded from the analyses.
Replication	Except the construction of scRNA-seq/scTCR-seq/TCR-seq libraries, all the in vivo and in vitro experiments were performed independently at least 2 times. For the scRNA-seq/scTCR-seq/TCR-seq libraries, each library sample was originated from the pooled target cells of 8-12 mice. And the key scRNA-seq/scTCR-seq/TCR-seq data were validated by independent flow cytometry assays. All results described in the study can be reproduced.

Randomization	For animal experiments, control and treatment groups were delineated in each figure and figure legend. Before the treatment, tumor-engrafted mice were evenly distributed into each group based on the mean tumor volume of the whole cohort so that the standard deviation was equal across all groups.
Blinding	Experiments in the study were not performed in a blinded manner due to no involvement of subjective measurements. Besides, objective readouts were gained as experimental outcomes in the study. Thus, the data in the study were not prone to subjective evaluation.

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

Materials & experimental systems

n/a	Involved in the study
☐	☒ Antibodies
☐	☒ Eukaryotic cell lines
☒	☐ Palaeontology and archaeology
☐	☒ Animals and other organisms
☒	☐ Clinical data
☒	☐ Dual use research of concern
☒	☐ Plants

Methods

n/a	Involved in the study
☒	☐ ChIP-seq
☐	☒ Flow cytometry
☒	☐ MRI-based neuroimaging

Antibodies

| Antibodies used | Flow cytometry antibodies used in mouse studies (company, cat number, clone, dilution):
anti-mouse CD8 (BioLegend, 100743, clone 53-6.7, 1:200), anti-mouse CD4 (BioLegend, 100553, clone RM4-5, 1:200), anti-mouse CD45 (BioLegend, 103122, clone 30-F11, 1:200), anti-mouse CD45.1 (BioLegend, 110706, clone A20, 1:200), anti-mouse Vα2 (BioLegend, 127810, clone B20.1, 1:200), anti-mouse MHC-I (BioLegend, 114614, clone 28-8-6), anti-mouse MHC-II (BioLegend, clone M5/114.15.2), anti-mouse F4/80 (BioLegend, 123110, clone BM8, 1:200), anti-mouse CD11b (BioLegend, 101211, clone M1/70, 1:200), anti-mouse CD11c (BioLegend, 117308, clone N418, 1:200), anti-mouse Ly-6C (BD Biosciences, 562737, clone AL-21, 1:200), anti-mouse H-2Kb bound to SIINFEKL antibody (BioLegend, 141606, clone 25-D1.16, 1:200), anti-mouse KLRG1 (BD Biosciences, 561621, clone 2F1, 1:200), anti-mouse CD127 (BioLegend, 158204, clone A7R34, 1:200), anti-mouse CD44 (BioLegend, 103047, clone IM7, 1:200), anti-mouse CD62L (BioLegend, 104418, clone MEL-14, 1:200), anti-mouse PD-1 (BioLegend, 135219, clone 29F.1A12, 1:200), anti-mouse Tim-3 (R&D systems , FAB1529P, clone 215008, 1:200), anti-mouse LAG-3 (BioLegend, 125208, clone C9B7W, 1:200), anti-mouse 2B4 (BioLegend, 133504, clone m2B4 (B6)458.1, 1:200), anti-mouse CD39 (BioLegend, 143804, clone Duha59, 1:200), anti-mouse Ly108 (BioLegend, 134610, clone 330-AJ, 1:200), anti-mouse GITR (BioLegend, 126312, clone DTA-1, 1:200), anti-mouse CD69 (BioLegend, 104512, clone H1.2F3, 1:200), anti-mouse CD103 (BioLegend, 121418, clone 2E7, 1:200), anti-mouse CD25 (BioLegend, 102028, clone PC61, 1:200), H-2Kb MuLV p15E Tetramer-KSPWFTTL-PE (MBL, TS-M507-1, 1:10), anti-mouse CD107a (BioLegend, 121606, clone 1D4B, 1:400), anti-mouse CD107b (BioLegend, 108504, clone M3/84, 1:400), anti-mouse IL-2 (BioLegend, 503824, clone JES6-5H4, 1:50), anti-mouse IFN-γ (BD Biosciences, 563376, clone XMG1.2, 1:100), anti-mouse TNF-α (BioLegend, 506108, clone TN3-19.12, 1:100), anti-mouse TCF-1 (Cell Signaling Technology, 6444S, clone C63D9, 1:400), donkey anti-rabbit polyclonal IgG (H+L) highly cross-adsorbed secondary antibody (Thermo Fisher, A-21206, 1:1000), anti-mouse Eomes (eBioscience, 25-4875-82, clone Dan11mag, 1:100), anti-mouse T-bet (BioLegend, 644808, clone 4B10, 1:100), anti-mouse TOX (Thermo Fisher, 12-6502-82, TXRX10, 1:100), anti-mouse Ki67 (BD Biosciences, 556027, 1:20) and anti-mouse GZMB (BioLegend, 372208, clone QA16A02, 1:100).

Flow cytometry antibodies used in human studies (company, cat number, clone, dilution):
anti-human CD45 (BioLegend, 304039, clone HI30, 1:200), anti-human CD8 (BioLegend, 300922, clone HIT8a, 1:200), anti-human CD4 (BioLegend, 317444, clone OKT4, 1:200), anti-human TNF-α (BioLegend, 376206, clone W19063E, 1:200), anti-human HLA-A2 (BioLegend, 343304, clone BB7.2, 1:200) and anti-human HLA-DR (BioLegend, 307617, clone L243, 1:200).

Blocking or depleting antibodies:
anti-mouse PD-L1 (BioXcell, clone 10F.9G2), isotype-matched control antibody (BioXcell, rat IgG2b, clone LTF-2), anti-mouse CD8 antibody (BioXell, clone 53-6.7), anti-mouse CD4 antibody (BioXell, clone GK1.5), anti-human CD8 antibody (BioXCell, clone OKT8), anti-human CD4 antibody (BioXCell, clone OKT4).

Antibodies for immunofluorescence or ELISA assays:
anti-actin (Cell Signaling Technology, 3134), anti-NDV P protein (provide by Dr. Guozhong Zhang, China Agricultural University), HRP-conjugated goat anti-human IgG antibody (Bioss Biotech). |
|---|---|
| Validation | The validation data of all the commercial antibodies can be found on the manufactures' websites.

Antibody (rabbit polyclonal antibody) specific to NDV P protein was provide by Dr. Guozhong Zhang (China Agricultural University) and was validated by previously published study (Xiao Li et al., Virulence, 2023, PMID: 36919461). |

Eukaryotic cell lines

Policy information about cell lines and Sex and Gender in Research

Cell line source(s)	MC38 cells (NM-S13) and MC38-OVA (NM-S13-TM56) were purchased from Shanghai Model Organisms Center. B16F10 cells (CRL-6475), 4T1 cells (CRL-2539) and A375 cells (CRL-1619) were purchased from ATCC. B16-GP cells were purchased from Beijing Biocytogen Co.Ltd, China.
Authentication	B16-GP cell line was authenticated by PCR assays with species-specific primers (Huang, Q. et al., Cell, 2022, PMID: 36208623; Xiao, M. et al, J Immunother Cancer, 2022, PMID: 35580929). The other commercial cell lines were authenticated by Shanghai Model Organisms Center or ATCC and validated by PCR assays with species-specific primers in our lab.
Mycoplasma contamination	All the cell lines in the study were tested negative for mycoplasma contamination.
Commonly misidentified lines (See ICLAC register)	There were no misidentified lines in the study.

Animals and other research organisms

Policy information about studies involving animals; ARRIVE guidelines recommended for reporting animal research, and Sex and Gender in Research

Laboratory animals	C57BL/6, BALB/c, OT-I transgenic and CD45.1+ congenic (strain B6.SJL-Ptprca Pepcb/BoyJ) mice were purchased from the Jackson Laboratories. P14 transgenic (carrying a transgenic T cell antigen receptor that recognizes H-2Db GP33-41 epitope) and SMARTA transgenic (carrying a transgenic T cell antigen receptor that recognizes I-Ab GP66-77 epitope) mice were gifts from Dr. Rafi Ahmed (Emory University). The CXCR5-GFP knock-in mice were were purchased from Beijing Biocytogen Co.Ltd, China. Immunodeficient NOD/ShiLtJGpt-Prkdcem26Cd52Il2rgem26Cd22/Gpt (NCG) mice were purchased from the GemPharmatech Co., Ltd of Nanjing. Mice of 6-10-week-old were used for animal experiments.
Wild animals	There were no wild animals used in the study.
Reporting on sex	Both sexes were randomly allocated to into control and treatment groups in the study, except only female BALB/c mice were used for the engraftment of 4T1 breast cancer cells.
Field-collected samples	There were no samples collected from the field in the study.
Ethics oversight	All experiments involving C57BL/6, BALB/c, P14, SMARTA, OT-I, CXCR5-GFP knock-in and CD45.1+ congenic mice were carried out in accordance with procedures approved by the Institutional Animal Care and Use Committees of Third Military Medical University. All experiments involving the generation and characterization of humanized NCG mice were approved by an Institutional Animal Care and Use Committee (IACUC) at the Model Animal Research Center in Nanjing University (AP# LY-01).

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Plants

Seed stocks	Does not apply in the study.
Novel plant genotypes	Does not apply in the study.
Authentication	Does not apply in the study.

Flow Cytometry

Plots

Confirm that:

☒ The axis labels state the marker and fluorochrome used (e.g. CD4-FITC).

☒ The axis scales are clearly visible. Include numbers along axes only for bottom left plot of group (a 'group' is an analysis of identical markers).

☒ All plots are contour plots with outliers or pseudocolor plots.

☒ A numerical value for number of cells or percentage (with statistics) is provided.

Methodology

Sample preparation

Lymphocytes in spleens were harvested by mashing the spleens through cell strainer (BD Falcon). Lymphocytes in the peripheral blood were obtained by using FICOLL (TBD, LTS107701) density gradient. To obtain liver-resident lymphocytes, mice were euthanized and perfused. Then, livers were dissected and mechanically minced. Liver-resident lymphocytes were acquired using Percoll (GE Healthcare, 17-0891-09) density gradient. To obtain MC38 or MC38-OVA or 4T1 tumor-infiltrating lymphocytes (TILs), tumors were mechanically minced, digested using with 1 mg/mL collagenase I (Sigma, c0130) and mashed through filters. Then, TILs were enriched using Percoll (GE Healthcare, 17-0891-09) density gradient. To harvest B16F10 or B16F10-GP TILs, tumors were mechanically minced and TILs were enriched using Percoll (GE Healthcare, 17-0891-09) density gradient. To obtain suspended tumor cells of A375 melanoma, tumors were mechanically minced, digested using with 1 mg/mL collagenase I (Sigma, c0130) and mashed through filters.

Instrument

Flow cytometry data were acquired using FACSCanto II (BD Biosciences) or FACSFortesa (BD Biosciences). Cell sorting experiments were performed with BD FACSAria III (BD Biosciences).

Software

BD FACSDiva software was used for data acquisition and FlowJo (version 10.4.0) was used for data analysis.

Cell population abundance

For the determination of sample purity, sorted target cells were collected by the BD FACSAria III (BD Biosciences) using the same gating strategy. And the purity of the collecting gate reached at least 95%.

Gating strategy

The cells were gated on FSC-A/SSC-A basis on the location known to immune cells or tumor cells, followed by excluding dead cells using live-dead dye negative gating. Next, the doublets were excluded by FSC-W/FSC-H and SSC-W/SSC-H. Then, target immune cells (e.g., T cells, DCs, macrophages) and tumor cells were gated according to well-known lineage and functional markers for further analyses.

☒ Tick this box to confirm that a figure exemplifying the gating strategy is provided in the Supplementary Information.
